The KeRF Programming Language Work In Progress

John Earnest

December 4, 2015

This manual is a reference guide to KeRF, a concise multi-paradigm language with an emphasis on high-performance data processing. For the latest information and licensing inquiries, please consult:

1 Introduction

KeRF is a programming language built on pragmatism, borrowing ideas from many popular tools. The syntax of KeRF will be familiar enough to anyone who has programmed in C, Python or VBA. Data is described using syntax from JSON (JavaScript Object Notation), a text-based data interchange format. Queries to search, sort and aggregate data can be performed using SQL syntax. KeRF's built-in commands have aliases which allow programmers to use names and terms they are already used to.

Beneath this friendly syntax, KeRF exposes powerful ideas inspired by the language APL and its descendants. APL has a well-earned reputation for extreme concision, and with practice you will find that KeRF similarly permits you to say a great deal with a few short words. Coming from other programming languages, you may be surprised by how much you can accomplish without writing loops, using conditional statements or declaring variables. KeRF provides a fluid interface between your intentions and your data.

1.1 Conventions

Throughout this manual, the names of functions and commands will be shown in a monospaced font. Transcripts of terminal sessions will be shown with sections typed by the user in blue:

```
KeRF> range 6
  [0, 1, 2, 3, 4, 5]
KeRF> sum(5, range 6)
  20
```

1.2 Using the REPL

A Read-Evaluate-Print Loop (REPL) is an interactive console session that allows you to type code and see results. The REPL is the main way you will be interacting with KeRF. If KeRF is in the current directory, you can start the REPL by typing ./kerf and pressing return, and if if you have installed KeRF in your path, you can simply type kerf. The rest of this discussion will assume the latter case.

1.2.1 Command-Line Arguments

KeRF accepts several command-line flags to control its behavior. Throughout this manual we will be using the -q flag for some examples to avoid showing the KeRF startup logo for the sake of brevity.

Flag	Arguments	Behavior	
-q	-	Suppress the startup banner.	
-1	-	Enable debug logging.	
-e	String Expression	Execute an expression.	
-X	String Expression	Evaluate an expression and print the result.	
-p	Port Number	Specify a listening port for starting an IPC server.	

Summary of Command-Line Flags

The -e and -x flags differ by whether or not they display the result of a calculation. Either will exit the interpreter when complete:

```
> kerf -x "2+3"
5
> kerf -e "2+3"
>
```

If you provide a filename as a command-line argument, the contents of that file will be executed before opening the REPL. You may wish to conclude scripts with exit(0) so that they execute and then self-terminate:

You could also accomplish the same by using -x and load:

```
> kerf -x "load 'example.kerf'"
```

1.2.2 The REPL

The REPL always begins with the KeRF> prompt. Type an expression, press return and the result will be printed, followed by an empty line. If an expression returns null, it will appear as an empty line. Trailing whitespace will generally be elided from REPL transcripts in this manual.

```
KeRF> 1+3 5 7
  [4, 6, 8]

KeRF> null

KeRF>
```

If you type several expressions separated by semicolons (;), each will be executed left to right and the value returned by the final expression will be printed. An empty expression returns null, so if you end a statement with a semicolon it will effectively suppress printing the result. Transcripts in this manual will often use this technique for the sake of brevity.

```
KeRF> one: 1; two: 2
  2
KeRF> one
  1
KeRF> a: 3 5 7;
KeRF>
```

If you type an expression with an unbalanced number of [, (or $\{$, the REPL will prompt you with > to complete the expression on the next line. Remember, newlines and semicolons are always equivalent:

```
KeRF> [1 2 3
> 4 5 6]
  [[1, 2, 3],
  [4, 5, 6]]
```

1.3 Examples

The following are a few short KeRF snippets to provide a taste of how the language can be employed.

Are two strings anagrams?

```
def are_anagrams(a, b) {
    return (sort a) match (sort b)
}
```

```
KeRF> are_anagrams("baton", "stick")
   0
KeRF> are_anagrams("setecastronomy","toomanysecrets")
   1
```

Gather simple statistics for random data using SQL syntax:

```
KeRF> data: {{a: rand(100, 5)}};
KeRF> SELECT count(a) AS items, avg(a) AS average FROM data

items average
100 1.82
```

Load a text file and interactively query it:

```
KeRF> characters: tolower flatten lines "flour.txt"
  "flour is a powder made by grinding uncooked cereal grains or other seeds or roots (like cassava). it is the main ingredient of bread, which is a staple food for many cultures, making the availability o..."
KeRF> sum characters in "aeiou"
  182
KeRF> count characters
  540
KeRF> 5 take `" " explode characters
  ["flour", "is", "a", "powder", "made"]
```

2 Installation

Pre-compiled evaluation copies of KeRF for Linux and OSX can be obtained from the project's public page on GitHub. Currently, evaluation copies expire periodically. KeRF is gaining new features frequently, so make sure you keep your installation up to date.

https://github.com/kevinlawler/kerf

2.1 Installing (Evaluation)

Fetch a local copy of the KeRF repository using git clone:

```
/Users/john/Desktop> git clone https://github.com/kevinlawler/kerf.git
Cloning into 'kerf'...
remote: Counting objects: 538, done.
remote: Total 538 (delta 0), reused 0 (delta 0), pack-reused 538
Receiving objects: 100% (538/538), 29.26 MiB | 1.65 MiB/s, done.
Resolving deltas: 100% (225/225), done.
Checking connectivity... done
/Users/john/Desktop> cd kerf/
/Users/john/Desktop/kerf>
```

The binaries located in the /KerfREPL/linux and /KerfREPL/osx directories are for 64-bit Linux and OSX, respectively. They are statically linked and include all library dependencies. Installation is as simple as placing the binary in a desired directory. Let's place it in a directory called /opt/kerf so that it is accessible by all users. It will be necessary to use the sudo command when creating this directory, as the base directory is owned by root:

```
/Users/john/Desktop> sudo mkdir /opt/kerf
Password:
/Users/john/Desktop> sudo cp KerfREPL/osx/kerf /opt/kerf/
/Users/john/Desktop> cd /opt/kerf
/opt/kerf> ls
kerf
```

You can then invoke it from the command line. The -q option (quiet) suppresses the KeRF logo at startup, for the purposes of brevity in these transcripts.

```
/opt/kerf> ./kerf -q
KeRF> 2+3
5
KeRF> exit(0)
/opt/kerf>
```

From time to time, you should use the command git pull from within the directory you created via git clone to fetch the latest build of KeRF from this repository. Then simply repeat the above steps to move the fresh binary into its normal resting place.

2.2 Installing (Building from Source)

If you have been granted access to the KeRF source code, you can build your own binaries. From the base source directory, invoke make clean to remove any temporary or compiled files and then make to build a fresh set of binaries for your OS:

```
/Users/john/Desktop/kerf-source> make clean
find manual/ -type f -not -name '*.tex' | xargs rm
rm -f -r kerf kerf_test .//obj/*.o
/Users/john/Desktop/kerf-source> make
clang -rdynamic -m64 -w -Os -c alter.c -o obj/alter.o
...
/Users/john/Desktop/kerf-source>
```

This process will produce a kerf executable in the source directory. You can then follow the steps described in the above section to place this in a directory accessible by other users or simply run it in place.

2.3 Adding KeRF to your Path

You may wish to add the KeRF binary to your PATH so that it can be accessed more easily. If you've placed the binary in the directory /opt/kerf/, edit ~/.profile and add the following line:

```
export PATH=/opt/kerf/: $PATH
```

Open a fresh terminal or type source ~/.profile and you should now be able to invoke the kerf command from any directory.

3 Terminology

KeRF uses terminology from databases, statistics and array-oriented programming languages like APL. This section will serve as a primer for concepts which may seem unfamiliar.

3.1 Atomicity

Atomicity describes the manner in which values are *conformed* by particular functions.

A function which is not atomic will simply be applied to its arguments, behaving the same whether they are lists or atoms. enlist is not atomic:

```
KeRF> enlist 4
  [4]
KeRF> enlist [1, 9, 8]
  [[1, 9, 8]]
```

A unary function which is *atomic* will completely decompose any nested lists in the argument, operate on each atom separately, and then reassemble these results to match the shape of the original argument. Another way to think of this is that atomic functions "penetrate" to the atoms of their arguments. not is atomic:

```
KeRF> not 1
0
KeRF> not [1, 0, 0, 1, 0]
  [0, 1, 1, 0, 1]
KeRF> not [1, 0, [1, 0], [0, 1], 0]
  [0, 1, [0, 1], [1, 0], 1]
```

Things get more interesting when dealing with *fully atomic* binary functions. The shapes of the arguments do not have to be identical, but they must recursively *conform*. Atoms conform with atoms. Lists conform with atoms and vice versa. Lists only conform with other lists if their lengths match and each successive pairing of their elements conforms. add is fully atomic:

```
KeRF> add(1, 2)
3
KeRF> add(1 3 5, 10)
[11, 13, 15]
KeRF> add(1 2 3, 4 5 6)
[5, 7, 9]
```

3.2 Combinators

In the context of KeRF, a *combinator* is an operator which controls how a *function* is applied to *values*. Combinators express abstract patterns which recur frequently in programming. For example, consider the following loop:

```
function mysum(a) {
     s: 0
     for(i: 0; i < len(a); i: i+1) { s: add(s, a[i]) }
     return s
}</pre>
```

We're iterating over the indices of the list x from left to right, accumulating a result into the variable s. On each iteration, we take the previous s and combine it with the current element of a via the function add. This pattern is captured by the combinator fold, which takes a function as a left argument and a list as a right argument:

```
KeRF> add fold 37 15 4 8 64
```

Think of fold as applying its function argument between the elements of its list argument:

```
KeRF> (((37 add 15) add 4) add 8)
64
```

In this particular case we could have simply used the built-in function sum, but fold can be applied to any function- including functions you define yourself. Combinators are generally much more concise than writing explicit loops, and by virtue of having fewer "moving parts" avoid many classes of potential mistake entirely. If you use fold it isn't possible to have an "off-by-one" index error accessing elements of the list argument and several useful base cases are handled automatically. Familiarize yourself with all of KeRF's combinators-with practice, you may find you hardly ever need to use for, do and while loops at all!

KeRF understands the patterns combinators express and can sometimes perform dramatic optimizations when they are used in particular combinations with built-in functions or data with specific properties:

```
KeRF> timing(1);
KeRF> max fold range 50000
49999
    0 ms
KeRF> {[a,b] max(a, b)} fold range 50000
49999
    3.2 s
```

The former example allows KeRF to recognize the opportunity for short-circuiting max fold because the result of range is sorted. When folding a user-declared lambda, it must construct and then reduce the entire list.

3.3 Matrix

A matrix is a vector of vectors of uniform length and type. For example, the following is a matrix:

```
[[1, 2, 3],
[4, 5, 6],
[7, 8, 9]]
```

But this is not a matrix, because the rows are not of uniform length:

```
[[1, 2],
[3, 4, 5, 6],
[7, 8, 9]]
```

3.4 Valence

A function's valence is the number of arguments it takes. For example, add is a binary function which takes two arguments and thus has a valence of 2. not, on the other hand, is a unary function which takes a single argument and thus has a valence of 1. The term draws an analogy to linguistics and in turn chemistry, describing the way words and molecules form compounds.

3.5 Vector

A *vector* is a list of elements with a uniform type. If a list contains more than one type of element it is sometimes referred to as a *mixed-type list*. Vectors can store data more densely than mixed-type lists and as a result are often more efficient.

4 Datatypes

4.1 Numbers

KeRF has two numeric types: *integers* (or "ints") and *floating-point numbers* (or "floats"). The results of numeric operations between ints and floats will coerce to floats, and some operators always yield floating-point results.

Integers consist of a sequence of digits, optionally preceded by + or -. They are internally represented as 64-bit signed integers and thus have a range of $-(2^{63})$ to $2^{63} - 1$.

```
42
010
+976
-9000
```

Integers can additionally be one of the special values INF, -INF or NAN, used for capturing arithmetic overflow and invalid elements of an integer vector:

Floats consist of a sequence of digits with an optional sign, decimal part and exponent. They are based on IEEE-754 double-precision 64-bit floats, and thus have a range of roughly $1.7 * 10^{\pm 308}$.

```
1.0
-379.8
-.2
.117e43
```

Floats can additionally be one of the special values nan, -nan, inf or -inf. nan has unusual properties in KeRF compared to most other languages. The behavior is intended to permit invalid results to propagate across calculations without disrupting other valid calculations:

```
KeRF> nan == nan
1
KeRF> nan == -nan
1
KeRF> 5/0
inf
KeRF> 0/0
nan
KeRF> -1/0
-inf
```

4.2 Lists and Vectors

Lists are ordered containers of heterogenous elements. Lists have several literal forms. A sequence of numbers separated by whitespace is a valid list. This is an "APL-style" literal:

```
1 2 3 4
47 49
```

Alternatively, separate elements with commas (,) or semicolons (;) and enclose the list in square brackets for a more explicit "JSON-style" literal:

```
[1, 2, 3]
[4;5;6]
[42]
```

This manual will use both styles throughout the examples. Naturally, these styles can be nested together. The following examples are equivalent:

```
[1 2,3 4,5,6]
[[1, 2], [3, 4], 5, 6]
[[1;2], [3;4], 5, 6]
```

If a list consists entirely of items of the same type, it is a *vector*. Vectors can be represented more compactly than mixed-type lists and thus are more cache-friendly and provide better performance. KeRF has special optimizations for vectors of timestamps, characters, floats and integers.

Vector and list types each have their own special symbol for emptiness:

```
KeRF> 0 take 1 2 3
    INT[]
KeRF> 0 take 1.0 2 3
    FLOAT[]
KeRF> 0 take "ABC"
    ""
KeRF> 0 take [now(),now()]
    STAMP[]
KeRF> 0 take [1,"A"]
    []
```

4.3 Strings and Characters

KeRF character literals begin with a backtick (`) followed by double-quotes (") or single-quotes (') surrounding the character. Character literals which do not contain escape sequences may omit the quotation marks.

```
`A
`'B'
```

KeRF supports all JSON string escape sequences, and additionally an escape for single-quotes:

```
// double quote
-1/11
            // single quote
- "/\"
            // reverse solidus
- 11//11
            // solidus
`"\b"
            // backspace
`"\f"
            // formfeed
`"\n"
            // newline
`"\r"
            // carriage return
`"\t"
            // horizontal tab
`"\u0043"
            // 4-digit unicode literal
```

The built in function char can convert a number into an equivalent character:

```
KeRF> char 65
"A"
```

Strings are lists of characters, and qualify as vectors. Strings are simply enclosed in double-quotes (") or single-quotes (").

```
"Hello, World!"
'goodbye,\ncruel world...'
```

4.4 Timestamps

Timestamps, or simply "stamps", are a flexible datatype which can represent dates, times, or a complete date-time. Times are internally represented in UTC at **nanosecond granularity**. Timestamp literals use a format similar to ISO-8601 except periods (.) are used as date field separators instead of dashes (-).

Timestamps can be compared using the same operators as numeric types. The special builtin stamp_diff should be used for calculating the interval between timestamps:

```
KeRF> 2015.04.02 < 2015.05.01
   1
KeRF> stamp_diff(2015.05.03, 2015.05.01)
   172800000000000
```

KeRF provides special literals for relative date-times:

These can also be combined as a single unit. For example,

```
KeRF> 2015.01.01 + 2m + 1d
  2015.03.02
KeRF> 2015.01.01 + 2m1d
  2015.03.02
KeRF> 2015.01.01 - 1h1i1s
  2014.12.31T22:58:59.000
```

Indexing is overloaded for timestamps to permit easy extraction of fields. The date and time fields produce a stamp and other fields produce an integer:

```
KeRF> d: now();
KeRF> d[["date", "time"]]
  [2015.11.14, 23:11:18.154]
KeRF> d[["month", "day", "hour", "minute"]]
  [11, 14, 23, 11]
KeRF> d[["year", "month", "day", "hour", "minute"]]
  [2015, 11, 14, 23, 11]
KeRF> d[["second", "millisecond", "nanosecond"]]
  [18, 154, 154858000]
```

4.5 Maps and Tables

A *Map* is an associative data structure which binds *keys* to *values*. KeRF maps are a generalization of JSON objects. Map literals are enclosed in a pair of curly braces ({ and }), and contain a series of comma delimited key-value pairs separated by a colon (:). JSON object syntax requires keys to be enclosed in double-quotes, but KeRF maps permit using single-quotes or bare identifiers.

```
{"a": 10, "b": 20} // JSON style
{'a': 10, 'b': 20} // optional single-quotes
{a: 10, b: 20} // bare identifiers
```

A *Table* is a map in which each value is a list of equal length. Tables are enclosed in two pairs of curly braces ({{ and }}) and otherwise syntactically resemble maps. If non-list values are provided, they will be wrapped in lists. Values can also be omitted entirely to produce a table with empty columns.

```
{{a: 1 2, b: 3 4}} // columns contain [1,2] and [3,4] 
{{a: 1, b: 2}} // columns contain [1] and [2] 
{{a, b}} // empty columns
```

If tables are serialized to JSON, KeRF will insert a key is_json_table- this permits tables to survive round-trip conversion:

```
KeRF> json_from_kerf {{a: 1 2, b: 3 4}}
"{\"a\":[1,2],\"b\":[3,4],\"is_json_table\":[1]}"
```

The builtins xkeys and xvals can be used to extract a list of keys or values from a map or table. The builtin map produces a map from a list of keys and a list of values.

```
KeRF> xkeys {a: 10 11 12, b: 20 21}
    ["a", "b"]
KeRF> xkeys {{a:1, b:2}}
    ["a", "b"]
KeRF> xvals {a: 10 11 12, b: 20 21}
    [[10, 11, 12], [20, 21]]
KeRF> xvals {{a:1, b:2}}
    [[1], [2]]
KeRF> map(["a","b"], [37, 99])
    {a:37, b:99}
```

Many primitive operations penetrate to the values of maps and tables:

```
KeRF> 3 + {a: 10, b: 20}
a:13, b:23
KeRF> 3 + {{a: 10, b: 20}}
a b
13 23
```

4.6 Special Identifiers

KeRF uses reserved words to identify a number of special values.

The words true and false are boolean literals, equivalent to 1 and 0, respectively:

```
KeRF> true
   1
KeRF> false
   0
```

Inside a function, the words self or this may be used to refer to the current function. This is particularly useful for performing recursive calls in anonymous "lambda" functions:

```
KeRF> def foo(x) { return [this, self, x] }
   {[x] return [this, self, x]}
KeRF> foo(9)
   [{[x] return [this, self, x]}, {[x] return [this, self, x]}, 9]
```

The words nil or null may be used to refer to a null value:

```
KeRF> nil

KeRF> null

KeRF> kerf_type_name nil
    "null"

KeRF> kerf_type_name null
    "null"
```

The word root is a reference to KeRF's global scope. It contains all the variables which have been defined or referenced:

```
KeRF> root
{}
KeRF> a: 24
24
KeRF> b
{}
KeRF> root
{a:24, b:{}}
```

4.7 Index and Enum

Indexes and Enumerations are special lists which perform internal bookkeeping to improve the performance of certain operations.

An *Enumeration* performs *interning*. It keeps only one reference to each object and stores appearances as fixed-width indices. It is useful for storing repetitions of strings and lists, which cannot otherwise efficiently be stored as vectors. In all other respects an Enumeration appears to be a list. To create an Enumeration, use hashed or the unary # operator:

```
KeRF> a: hashed ["cherry", "peach", "cherry"]
  #["cherry", "peach", "cherry"]
KeRF> kerf_type_name a
  "enum"
```

Not only do Enumerations reduce the memory footprint of lists with a large number of repeated elements, they permit dramatically faster sorting. There is no benefit to making an Enumeration out of a vector of integers or floats.

```
KeRF> samples: {[x] rand(x, ["cherry", "peach", "zucchini"])};
KeRF> s1: samples(1000);
KeRF> s2: samples(10000);
KeRF> s3: samples(100000);
KeRF> timing 1
 1
KeRF> sort s1;
    2 ms
KeRF> sort s2;
    15 ms
KeRF> sort s3;
    134 ms
KeRF> sort hashed s1;
    0 ms
KeRF> sort hashed s2;
   4 ms
KeRF> sort hashed s3;
    28 ms
```

An *Index* is a list augmented with a B-Tree. This permits more efficient lookups and range queries. Do not use an index for data that will always be sorted in ascending order- KeRF tracks sorted lists internally. To create an Index, use indexed or the unary = operator:

```
KeRF> b: indexed 3 9 0 7
=[3, 9, 0, 7]
KeRF> kerf_type_name b
  "sort"
```

5 Syntax

5.1 Expressions

Calling (or *applying*) a function in KeRF resembles most languages- use the name of the function followed by a parenthesized, comma-separated list of arguments:

```
KeRF> add(1, 2)
3
```

If a function takes exactly one argument, the parentheses are optional. We call this style "prefix" function application:

```
KeRF> negate(3)
  -3
KeRF> negate 3
  -3
```

This syntax makes it easy to "chain" together a series of unary functions:

```
KeRF> last sort unique "ALPHABETICAL"
    "T"
KeRF> last(sort(unique("ALPHABETICAL")))
    "T"
```

If a function takes no arguments, you must remember to include parentheses- otherwise the function will be returned as a value instead of called:

```
KeRF> exit
  exit
KeRF> exit()
>
```

If a function takes exactly two arguments, it can be placed between the first and second argument as an "infix" operator:

```
KeRF> 1 add 2
3
```

Many of the most frequently used functions have symbolic aliases. For example, + can be used instead of add and * can be used instead of times. There is no functional difference between the spelled-out names for these functions and the symbols.

```
KeRF> 3 * 5
   15
KeRF> *(3, 5)
   5
KeRF> 3 + 5
   8
KeRF> +(3, 5)
   5
```

Operators do not have precedence in KeRF. Expressions are evaluated strictly from right to left unless explicitly grouped with parentheses:

```
KeRF> 3 * 4 + 1

15

KeRF> 4 + 1 * 3

7

KeRF> (4 + 1) * 3

15
```

KeRF's flexible syntax often provides many alternatives for writing the same expression. Select the arrangement that you feel is most clear. Adding parentheses to confusing-seeming expressions never hurts!

```
KeRF> 0.5 * 3**2
4.5
KeRF> times(1/2, 3**2)
4.5
KeRF> divide(1, 2) * exp(3, 2)
4.5
KeRF> ((1 / 2) * (3 ** 2))
4.5
```

Symbol	Unary Function	Binary Function	
-	negate	minus	
+	transpose	add	
*	first	times	
/	reverse	divide	
	len (length)	maxes/or	
^	enumerate	take	
%	distinct	mod (modulus)	
&	part (partition)	mins/and	
?	which	rand (random)	
#	hashed	join	
!	not	map (make map)	
~	atom (is atom?)	match	
=	indexed	equals	
<	ascend	less	
>	> descend greater		
\		lsq	
<= lesseq		lesseq	
>= greatereq		greatereq	
==		equals	
!=		noteq	
<>		noteq	
**		exp	
_	floor		
	eval (evaluate)		
:	ident (identity)		

Symbolic Aliases of Built-in Functions

5.2 Indexing

KeRF has a uniform syntax for accessing elements of lists, maps and tables. Use square brackets to the right of a variable name or expression with an index or key to loop up:

```
KeRF> 3 7 15[1]
  7
KeRF> {a: 24, b: 29}["a"]
  24
```

If the provided index or key does not exist, indexing will return an appropriate type-specific null value, as provided by the type_null built-in function:

```
KeRF> 3 7 15[9]
NAN
KeRF> 3 7 15[-1]
NAN
KeRF> "ABC"[9]
```

Floating-point indices to lists will be truncated, for convenience:

```
KeRF> 3 7 15[0.5]

3

KeRF> 3 7 15[1.6]

7
```

Indexing is right-atomic. If the indices are a list, the indexing operation will accumulate a list of results:

```
KeRF> "ABC" [2 1 0 0 2 3 0 0 1]

"CBAAC AAB"

KeRF> 34 19 55 32[0 1 0 1 2 2]

[34, 19, 34, 19, 55, 55]
```

One application of this type of collective indexing is the basis of sort:

```
KeRF> a: 27 15 9 55 0
  [27, 15, 9, 55, 0]
KeRF> a[ascend a]
  [0, 9, 15, 27, 55]
```

The shape of the result of indexing will always match the shape of the indices. Consider this example, where we index a list with a 2x2 matrix and get back a 2x2 matrix:

```
KeRF> 11 22 33 44[[0 1, 2 3]]
  [[11, 22],
  [33, 44]]
```

Indexing a particular element from a multidimensional structure requires several indexing operations:

```
KeRF> [11 22, 33 44][0][1]
33
```

5.3 Assignment

KeRF uses the colon (:) as an assignment operator, unlike the convention of "=" from many other programming languages. SQL uses = as a comparison operator, JSON uses : as an assignment operator in map literals and KeRF syntax attempts to be a superset of both JSON and SQL.

Values may be assigned to variables with: and retrieved by using the variable name. Note that uninitialized variables behave as containing an empty map:

```
KeRF> a
  {}
KeRF> a: 3 7 19
  [3, 7, 19]
KeRF> a
  [3, 7, 19]
KeRF> a[1]
  7
```

Assignment may be combined with indexing to assign to specific cells of a list or keys of a map:

```
KeRF> a: range 4
  [0, 1, 2, 3]
KeRF> a[1]: 99
  [0, 99, 2, 3]
KeRF> a
  [0, 99, 2, 3]
KeRF> b: {bravo: 3, tango: 6};
KeRF> b["bravo"]: 99
  {bravo:99, tango:6}
```

Note KeRF's copy-on-write semantics:

```
KeRF> a: 0 1 2 3;
KeRF> b: a
  [0, 1, 2, 3]
KeRF> b[1]:99
  [0, 99, 2, 3]
KeRF> a
  [0, 1, 2, 3]
```

As with indexing, it is possible to perform collective "spread" assignment:

```
KeRF> a: 8 take 0
  [0, 0, 0, 0, 0, 0, 0, 0]
KeRF> a[1 2 5]:99
  [0, 99, 99, 0, 0, 99, 0, 0]
KeRF> b: 8 take 0
  [0, 0, 0, 0, 0, 0, 0, 0]
KeRF> b[1 2 5]:11 22 33
  [0, 11, 22, 0, 0, 33, 0, 0]
```

It is also possible to perform compound assignment, treating: like a combinator which takes a binary function as a left argument and applies the old value and the right argument to this function before performing the assignment:

```
KeRF> a: 0 0 0

[0, 0, 0]

KeRF> a#: 99

[0, 0, 0, 99]

KeRF> a join: 47

[0, 0, 0, 99, 47]
```

Compound assignment can be combined with indexing. Be warned, this can get confusing fairly quickly:

```
KeRF> a: 0 0 0
  [0, 0, 0]
  KeRF> a[1]+:4
  [0, 4, 0]
KeRF> a[0 2]+:1
  [1, 4, 1]
KeRF> a[0 2]#:55
  [[1, 55], 4, [1, 55]]
KeRF> a[0 2]#:3 4
  [[1, 55, 3], 4, [1, 55, 4]]
```

To modify an element of a multidimensional structure, use multiple indexing expressions:

```
KeRF> a: [11 22, 33 44]
  [[11, 22],
      [33, 44]]
KeRF> a[0][1]:99
  [[11, 99],
      [33, 44]]
KeRF> a[0 1][0]#:0
  [[[11, 0], 99],
      [[33, 0], 44]]
```

5.4 Control Structures

KeRF has a familiar, simple set of general-purpose control structures. Note that parentheses and curly braces are *never* optional for control structures.

5.4.1 Conditionals

KeRF has a C-style if statement with optional else if and else clauses. Like the C ternary operator (?:), KeRF if statements can be used as part of an expression. Each curly-bracketed clause returns the value of its last expression.

```
KeRF> if (2 < 3) { 25 } else { 32 }
25
KeRF> if (2 > 3) { 25 } else { 32 }
32
```

In KeRF, newlines are statement separators. Conditional statements spread across multiple lines must adhere to a specific, consistent indentation style:

```
if (a < b) {
        c : 100
} else if (a == b) {
        c : 200
} else {
        c : 400
}</pre>
```

Multiline conditionals *must not* be written with a newline before else if or else clauses. Implied (and undesirable) statement separators are shown in red:

Another incorrect indentation style:

```
if (a < b) { c : 100 };
else if (a == b) { c : 200 };
else { c : 400 };
```

5.4.2 Loops

KeRF provides a C-style for loop. The header consists of an initialization expression, a predicate and an updating expression. Note that the for loop itself returns null:

```
KeRF> for (i: 0; i < 4; i: i+1) { display 2*i }
0
2
4
6</pre>
KeRF>
```

KeRF also provides a C-style while loop. Note how in this example the loop returns its final calculation:

```
KeRF> t: 500; while(t > 32) { display t; t: floor t/2 }
500
250
125
62
31
KeRF>
```

If you simply want to repeat an expression a fixed number of times, use do:

```
KeRF> do (3) { display 42 }
42
42
KeRF>
```

If it is necessary to prematurely exit a loop, break the loop into its own function and use return.

Combinators and built-in functions can be substituted for loops in many situations:

```
KeRF> display mapdown range(0, 8, 2);
0
2
4
6
KeRF> {[t] t>32 } {[t] display t; floor t/2 } converge 500
500
250
125
62
31
KeRF> display mapdown take(3, 42);
42
42
```

5.4.3 Function Declarations

Functions can be declared using the function or def keywords and providing a parenthesized argument list. The final statement in a function body will be implicitly returned, and at any point in a function body you can instead use the return keyword to explicitly return.

```
function is_even(n) {
    return (n % 2) == 0
}

def divisible(a, b) {
    return (a % b) == 0
}
```

It is also possible to define anonymous functions as part of an expression. Some languages refer to these as *lambdas*, in reference to the lambda calculus, a formal model of computation based on the manipulation of anonymous functions. Anonymous functions are enclosed in curly brackets and may provide a square-bracketed ([and]) argument list:

```
KeRF> {[a, b] 2*a+b }(3, 5)
16
```

Storing a lambda in a variable is precisely equivalent to defining a function with function or def.

```
KeRF> divisible: {[a, b] (a % b) == 0 }
    {[a, b] (a % b) == 0}
KeRF> divisible(6, 3)
    1
KeRF> divisible(7, 2)
    0
```

KeRF uses lexical scope. This means that when variables are referenced, the definition textually closest to the reference will be used. The following example will print 25, because inner captures the definition of x in outer_1 when it is created. The definition of x in outer_2 is not used when this function is evaluated, nor is the top-level definition of x.

6 SQL

KeRF understands SQL (Structured Queried Language), a popular programmatic interface for relational databases. You can blend SQL-style queries with imperative statements and access the full range of KeRF predicates and logical operators while filtering and selecting results.

SQL keywords are not case-sensitive. To distinguish SQL keywords, the following examples will use uppercase exclusively. When describing the syntax of SQL statements, sections which can contain table names, field names or other types of subexpressions will be shown in **bold**. If a section is optional, it will be enclosed in bold square brackets ([and]). For example:

```
SELECT fields [ AS name ] FROM table ...
```

6.1 INSERT

INSERT is the simplest type of SQL statement. It is used for creating or appending to tables. INSERT can perform single or bulk insertions, the latter of which is much more efficient.

```
INSERT INTO table VALUES data
```

table can be a table literal or the name of a variable containing a table. In the latter case, the table will be modified in-place. data can be a list, matrix, map or table.

A single insertion can take values from a comma-separated, parenthesized list- this is special SQL syntax. Alternatively, use an ordinary square-bracketed KeRF list. You can also use a map, which more explicitly shows column names in the source data.

```
KeRF> INSERT INTO {{name, email, level}} VALUES ("bob", "b@ob.com", 7)
name
     email
               level
                   7
 bob b@ob.com
KeRF> INSERT INTO {{name, email, level}} VALUES ["bob", "b@ob.com", 7]
 name
      email
               level
                   7
 bob b@ob.com
KeRF> INSERT INTO {{name, email, level}} VALUES {name: "bob", level: 7, email: "b@ob.com"}
name
      email
               level
                   7
 bob b@ob.com
```

Note that a map which is to be inserted must have **exactly** the same key set as the destination table:

```
KeRF> INSERT INTO {{name, email, level}} VALUES {name: "bob", level: 7}

INSERT INTO {{name, email...

Length error
KeRF> INSERT INTO {{name, email, level}} VALUES {name: "bob", level: 7, hobbies: "needlepoint"}

INSERT INTO {{name, email...

Column error
```

Bulk insertions require either a matrix or a table:

An empty table will accept an INSERT from any map or table. List or matrix elements will be assigned default column names:

```
KeRF> INSERT INTO {{}} VALUES {legume: "Black Bean", dish: "Casserole"}

legume dish
Black Bean Casserole

KeRF> INSERT INTO {{}} VALUES employees

col col1 col2
bob b@ob.com 7
alice alice@gmail.com 9
jerry jerry@zombo.com 43
```

6.2 DELETE

DELETE is used for removing rows from a table. KeRF's columnar representation of tables means that a DELETE runs in linear time with respect to the number of rows in the table. Keep this in mind, and avoid repeated DELETEs over large (on-disk) datasets.

```
DELETE FROM table [ WHERE condition ]
```

table can be a table literal or the name of a variable containing a table. In the latter case, the table will be modified in-place. condition can be any KeRF expression, using the names of columns from table as variables. For more information about WHERE, see the discussion of SELECT.

If provided a reference to a table stored in a variable, DELETE will return the name of that variable. Otherwise, it will return the modified table itself:

```
KeRF> t: {{a:range(5000), b:rand(5000, 100.0)}}
 a b
 0 16.4771
 1 27.3974
 2 28.3558
 3 12.2126
 4 45.1148
 5 81.5326
 6
   95.726
 7
   38.1769
KeRF> count t
  5000
KeRF> DELETE FROM t WHERE b between [0, 50]
  "t"
KeRF> count t
  2474
KeRF> DELETE FROM \{\{a:range(10), b:rand(10, 100.0)\}\} WHERE \{a\%2\} = 1
 a b
 0 75.3017
      67.3
 4 19.4571
 6 66.3412
 8
    66.116
```

As you might expect, if you don't use a WHERE clause, DELETE will remove all the rows of a table:

```
KeRF> DELETE FROM t
"t"
KeRF> t

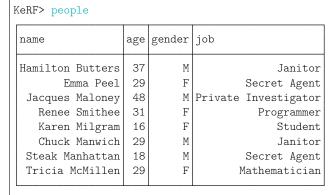

a b
```

6.3 SELECT

SELECT performs queries. It can be used to extract, aggregate or transform the contents of tables, producing new tables.

```
SELECT fields [ AS name ] FROM table
[ WHERE condition ]
[ GROUP BY aggregate ]
```

In its simplest form, SELECT can be used to slice a desired set of columns out of a table:

KeRF> SELECT name, gender FROM people

name	gender
Hamilton Butters Emma Peel Jacques Maloney Renee Smithee	M F M
Karen Milgram Chuck Manwich Steak Manhattan Tricia McMillen	F M M F

Selected columns can be renamed by specifying an AS clause for each:

```
KeRF> SELECT age AS person_age, gender AS sex FROM people
person_age sex
         37
              М
         29
               F
         48
              М
              F
         31
               F
         16
         29
              М
              М
         18
         29
               F
```

The wildcard * can be used to refer to all columns in a table. It is also possible to use a variety of collective functions like count or avg when selecting columns. When calculated columns are not given a name explicitly via AS, a default name will be supplied.

```
KeRF> SELECT count(*), sum(age), avg(age) AS average_age FROM people

col age average_age
8 237 29.625
```

It is possible to reference user-defined functions in a SELECT, but if they are not atomic you may need to explicitly apply them to elements of a column using combinators:

```
KeRF> revname: {[x] p:explode(`" ",x); implode(", ", reverse p)};
KeRF> from_dogyears: \{[x] \text{ if } (x < 21) \{ x/10.5 \} \text{ else } \{ x/4 \} \};
KeRF> SELECT revname mapdown name, from_dogyears mapdown age AS dog_age FROM people
 name
                    dog_age
 Butters, Hamilton
                        9.25
        Peel, Emma
                        7.25
  Maloney, Jacques
                        12.0
    Smithee, Renee
                        7.75
    Milgram, Karen
                    1.52381
    Manwich, Chuck
                        7.25
  Manhattan, Steak
                    1.71429
  McMillen, Tricia
                        7.25
```

6.3.1 WHERE

The WHERE clause permits filtering of results. Only rows which adhere to the contraints given as **condition** will be returned:

```
KeRF> SELECT * FROM people WHERE age > 30
 name
                       gender job
                   age
 Hamilton Butters
                    37
                                            Janitor
                            М
  Jacques Maloney
                    48
                            Μ
                              Private Investigator
                            F
    Renee Smithee
                    31
                                         Programmer
```

You can form a *conjunction* with several conditions by separating them with commas. Given a conjunction, the result is only selected if all conditions are satisfied. This is equivalent to performing a logical AND:

```
KeRF> SELECT * FROM people WHERE gender = "M", age > 30

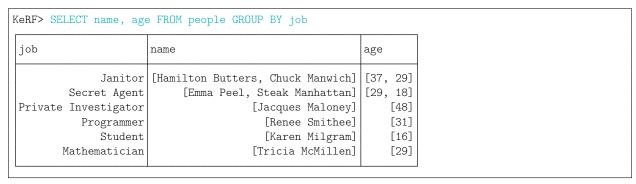

name age gender job

Hamilton Butters 37 M Janitor
Jacques Maloney 48 M Private Investigator
```

You can also form a conjuction by using the KeRF and operator, but in this case you must parenthesize subexpressions. Remember: KeRF evaluates expressions right to left unless otherwise parenthesized, so a = b and c > d is equivalent to a = (b and (c > d)):

6.3.2 GROUP BY

The GROUP BY clause can be used to gather together sets of rows which match on a particular column. In its simplest form, it behaves somewhat like the built-in function part. Note that the grouped-by column is included in the results:

You may often want to use collective functions to reduce each list of results:

```
KeRF> SELECT count(name) AS num, avg(age) FROM people GROUP BY job
job
                       num age
                        2 33.0
              Janitor
                        2 23.5
         Secret Agent
                        1 48.0
Private Investigator
           Programmer
                        1
                          31.0
                          16.0
              Student
                        1
        Mathematician
                          29.0
```

6.4 UPDATE

UPDATE modifies a table in-place, altering the values of some or all columns of rows which match a query.

```
UPDATE table SET assignments
[ WHERE condition ]
[ GROUP BY aggregate ]
```

In its simplest form, UPDATE transforms or reassigns one or more of the columns of the table. The right side of each clause of **assignments** can be any KeRF expression. Note that the SET clause can use the symbols = or : to represent assignment, for compatibility with familiar SQL engines. In practice, favor using : to avoid ambiguity.

Note that assignments are carried out left to right:

```
KeRF> UPDATE {{a:"First", b:"Second"}} SET a=b, b=a

a b

Second Second
```

An UPDATE can be restricted to only modify a specific subset of rows by using a WHERE clause. These function as in SELECT:

```
KeRF> UPDATE {{a:0 1 2, b:7 3 7}} SET b=99 WHERE b=7

a b
0 99
1 3
2 99
```

6.5 Joins

Steak Manhattan

Tricia McMillen

Emma Peel	29	UK
Jacques Maloney	48	France
Renee Smithee	31	France
Karen Milgram	16	USA
Chuck Manwich	29	Canada

6.5.1 Left Join

A left join includes every row of the left table (x), and adds any additional columns from the right table (y) by matching on some key column (z). Added columns where there is no match on z will be filled with type-appropriate null values as generated by type_null.

```
KeRF> t: {{a:1 2 2 3, b:10 20 30 40}}

a b
1 10
2 20
2 30
3 40

KeRF> u: {{a:2 3, c:1.5 3}}

a c
2 1.5
3 3.0

KeRF> left_join(t, u, "a")

a b c
1 10 nan
2 20 1.5
2 30 1.5
3 40 3.0
```

If z is a list, require a match on several columns:

```
KeRF> u: {{a:2 3, b:30 40, c:1.5 3}};
KeRF> left_join(t, u, ["a","b"])
a b c

1 10 nan
2 20 nan
2 30 1.5
3 40 3.0
```

If z is a map, associate columns from x as keys with columns from y as values, permitting joins across tables whose column names differ.

```
KeRF> u: {{z:2 3, c:1.5 3}};
KeRF> left_join(t, u, {'a':'z'})
a b c

1 10 nan
2 20 1.5
2 30 1.5
3 40 3.0
```

6.5.2 Asof Join

Behaves as left_join for the first three arguments. The fourth argument is a string, list or map indicating columns which will match if the values in y are less than or equal to x. Often this operation is applied to timestamp columns, but it works for any other comparable column type.

```
KeRF> t: \{\{a: 1 2 2 3, b: 10 20 30 40\}\}
 a b
 1 10
2 20
2 30
3 40
KeRF> u: {{b: 19 17 32 8, c: ["A","B","C","D"]}}
    Α
 19
 17 B
 32 C
  8 D
KeRF> asof_join(t, u, [], "b")
 a b
 1 10 D
 2 20 A
 2 30 A
 3 40 C
```

6.6 Limiting

If you wish to retrieve the first n items of a query, as in a SQL LIMIT clause, you can use the built-in function first:

But beware- if the result has fewer than n rows, this approach will replicate them. A better approach is to define a new function which takes the minimum of n and the length of the result:

6.7 Ordering

If you wish to sort tables along a column, as in a SQL ORDER BY clause, you can use the built-in functions ascend or descend along with indexing:

name	age	gender	job
Hamilton Butters	37	М	Janitor
Chuck Manwich	29	M	Janitor
Tricia McMillen	29	F	Mathematician
Jacques Maloney	48	M	Private Investigator
Renee Smithee	31	F	Programmer
Emma Peel	29	F	Secret Agent
Steak Manhattan	18	M	Secret Agent
Karen Milgram	16	F	Student

6.8 Performance

WHERE clauses have a special understanding of certain KeRF verbs and can achieve significant performance boosts in the right circumstances.

```
KeRF> n: 200000;
KeRF> i: range(n);
KeRF> v: rand(n, 100.0);
KeRF> iv: indexed v;
KeRF> find: {[x] select count(*) from {{i:i, v:x}} where v < 23.7};

KeRF> timing 1;
KeRF> find v;
    15 ms
KeRF> find iv;
    6 ms
```

For best results, order WHERE conjunctions to perform the largest reduction of data first, or take advantage of indexed or enum columns as early as possible:

```
KeRF> n: 200000;
KeRF> t: {{a: range(n), b: rand(n, 100.0), c: rand(n, 6)}}
 a b
 0
   82.268 2
 1 80.5227 0
 2 13.5797 1
 3 80.2291 3
 4 61.5329 3
 5 67.2546 1
 6 64.5684 5
 7 29.7027 2
KeRF> timing 1;
KeRF> select * from t where b > 50, c = 1;
   25 ms
KeRF> select * from t where c = 1, b > 50;
   13 ms
KeRF> select * from t where (c = 1) and (b > 50);
   14 ms
```

7 Input/Output

KeRF provides a rich set of built-in IO functions for displaying, serializing, importing and exporting data. Beyond the capabilities described here, KeRF provides a general purpose foreign-function interface- see the documentation for dlload.

7.1 General I/O

The function out(x) will print a string x to standard output. Non-string values are ignored:

```
KeRF> out "foo"
foo
KeRF> out 65
KeRF>
```

The function display(x) will print a display representation of data to standard output. Equivalent to out join(rep x, '\n'). A key difference between calling this function from the REPL and using the REPL's natural value printing is that display will print the entire result:

```
KeRF> range 50
  [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19,
20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37,
38, 39, 40, ...]
KeRF> display range 50
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19,
20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37,
38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49]
```

The function shell(x) will execute a string x containing a shell command as if from /bin/sh -c x and return the lines of the result:

```
KeRF> out implode("\n", shell("cal"))
   November 2015
Su Mo Tu We Th Fr Sa
1 2 3 4 5 6 7
8 9 10 11 12 13 14
15 16 17 18 19 20 21
22 23 24 25 26 27 28
29 30
KeRF> shell("echo Hello, World!")
   ["Hello, World!"]
```

7.2 File I/O

The function dir_ls lists the files and directories at a path. It can optionally provide full path names:

```
KeRF> dir_ls("/Users/john/Sites")
   [".DS_Store", ".localized", "images", "index.html", "subforum.php"]
KeRF> dir_ls("/Users/john/Sites", 1)
   ["\/Users\/john\/Sites\/.DS_Store"
    "\/Users\/john\/Sites\/.localized"
    "\/Users\/john\/Sites\/images"
    "\/Users\/john\/Sites\/index.html"
    "\/Users\/john\/Sites\/subforum.php"]
```

The function lines (filename, n) loads lines from a plain text file into a list of strings. The argument n is optional, and specifies the maximum number of lines to read.

```
KeRF> lines("example.txt")
  ["First line", "Second line", "Third line"]
KeRF> lines("example.txt", 2)
  ["First line", "Second line"]
```

The function write_text(filename, x) writes a raw string to a file, returning the number of bytes written. If x is not already a string it will be converted to one as by $json_from_kerf$. To perform the inverse of lines(), use write_text(filename, implode("\n", x)).

```
KeRF> write_text("example.txt", 5)
1
KeRF> write_text("example.txt", 99)
2
KeRF> shell("cat example.txt")
["99"]
```

KeRF has a proprietary binary serialization format. The function write_to_path(filename) writes a KeRF object to a file, creating it if necessary, and returns 0 if the operation was successful. Objects can then be reconstituted from binary files by calling read_from_path(filename).

KeRF also has built-in functions which make it easy to read and write common tabular data formats. read_table_from_delimited_file loads data, write_delimited_file_from_table writes data, and several wrapper functions are available which read and write CSV or TSV files using this functionality.

Finally, KeRF can load data from text files with fixed-width columns with read_table_from_fixed_file. See the built-in function reference discussion of this function for additional details.

7.3 Network I/O (IPC)

KeRF has a specialized remote procedure call system built on TCP which permits distributing tasks across multiple processes or machines. This is sometimes described as Inter-Process Communication (IPC). To spawn a KeRF process which listens for IPC calls, invoke kerf with the -p command-line argument and specify a TCP port number:

```
> ./kerf -p 1234
Kerf Server listening on port: 1234
KeRF>
```

The function open_socket(host, port) opens a connection to a remote KeRF instance at hostname host and listening on port and returns a connection handle. Both host and port must be strings. Once opened, a connection handle may be closed via close_socket(handle).

```
KeRF> open_socket("localhost", "1234")
4
```

The function send_async(handle, x) will send a string x to a remote KeRF instance without waiting for a reply. x will be evaled on the remote server, returning 1 on a successful send.

The function send_sync(handle, x) will send a string y to a remote KeRF instance, waiting for a reply. y will be evaled on the remote server, and the result will be returned.

```
KeRF> c: open_socket("localhost", "1234")
4
KeRF> send_async(c, "foo: 2+3")
1
KeRF> foo
{}
KeRF> send_sync(c, "[foo, foo]")
   [5, 5]
KeRF> send_sync(c, "sum range 1000")
499500
```

During IPC execution, the constant .Net.client contains the current client's unique handle:

```
KeRF> open_socket("localhost", "10101")
6
KeRF> send_sync(6, ".Net.client")
6
KeRF> .Net.client
0
```

If defined, an IPC server will call the single-argument function .Net.on_close with a client handle when that client closes its connection:

```
KeRF> .Net.on_close: {[x] out 'client closed: ' join (string x) join '\n'};
KeRF>
server: new connection from 127.0.0.1 on socket 6
client closed: 6
```

8 Built-In Function Reference

8.1 abs - Absolute Value

abs(x)

Calculate the absolute value of x. Atomic.

```
KeRF> abs -4 7 -2.19 NaN
[4, 7, 2.19, nan]
```

8.2 acos - Arc Cosine

acos(x)

Calculate the arc cosine (inverse cosine) of x, expressed in radians, within the interval [-1,1]. Atomic. The results of acos will always be floating point values.

```
KeRF> acos 0.5 -0.2 1
  [1.0472, 1.77215, 0]
KeRF> cos(acos 0.5 -0.2 1 4)
  [0.5, -0.2, 1, nan]
```

8.3 add - Add

add(x, y)

Calculate the sum of x and y. Fully atomic.

```
KeRF> add(3, 5)
8
KeRF> add(3, 9 15 -7)
  [12, 18, -4]
KeRF> add(9 15 -7, 3)
  [12, 18, -4]
KeRF> add(9 15 -7, 1 3 5)
  [10, 18, -2]
```

The symbol + is equivalent to add when used as a binary operator:

```
KeRF> 2 4 3+9
[11, 13, 12]
```

8.4 and - Logical AND

and(x, y)

Calculate the logical AND of x and y. This operation is equivalent to the primitive function min. Fully atomic.

```
KeRF> and(1 1 0 0, 1 0 1 0)
[1, 0, 0, 0]
KeRF> and(1 2 3 4, 0 -4 9 0)
[0, -4, 3, 0]
```

The symbol & is equivalent to and when used as a binary operator:

```
KeRF> 1 1 0 0 & 1 0 1 0 [1, 0, 0, 0]
```

8.5 ascend - Ascending Indices

ascend(x)

For a list x, generate a list of indices into x in ascending order of the values of x.

```
KeRF> t:5 2 3 1
  [5, 2, 3, 1]
KeRF> ascend t
  [3, 1, 2, 0]
KeRF> t[ascend t]
  [1, 2, 3, 5]
```

Strings are sorted in lexicographic order:

```
KeRF> ascend ["Orange", "Apple", "Pear", "Aardvark", "A"]
[4, 3, 1, 0, 2]
```

When applied to a map, ascend will sort the keys by their values and produce a list:

```
KeRF> ascend {"A":2, "B":9, "C":0}
["C", "A", "B"]
```

The symbol < is equivalent to ascend when used as a unary operator:

```
KeRF> <5 2 3 1
[3, 1, 2, 0]
```

8.6 asin - Arc Sine

asin(x)

Calculate the arc sine (inverse sine) of x, expressed in radians, within the interval [-1,1]. Atomic. The results of asin will always be floating point values.

```
KeRF> asin 0.5 -0.2 1

[0.523599, -0.201358, 1.5708]

KeRF> sin(asin 0.5 -0.2 1 4)

[0.5, -0.2, 1, nan]
```

8.7 asof_join - Asof Join

```
asof_join(x, y, k1, k2)
```

Perform a "fuzzy" left join. See **Joins**.

8.8 atan - Arc Tangent

atan(x)

Calculate the arc tangent (inverse tangent) of x, expressed in radians. Atomic. The results of atan will always be floating point values.

```
KeRF> atan 0.5 -0.2 1 4
  [0.463648, -0.197396, 0.785398, 1.32582]
KeRF> tan(atan 0.5 -0.2 1 4)
  [0.5, -0.2, 1, 4]
```

8.9 atlas - Atlas Of

atlas(x)

Create an atlas from a map. An atlas is the schemaless NoSQL equivalent of a table. Atlases are automatically indexed in such a way that all key-queries are indexed.

```
KeRF> atlas({name:["bob", "alice", "oscar"], id:[123, 421, 233]})
  atlas[{name:["bob", "alice", "oscar"], id:[123, 421, 233]}]
```

8.10 atom - Is Atom?

atom(x)

A predicate which returns 0 if x is a list, and 1 if x is a non-list (atomic) value.

```
KeRF> atom `"A"
1
KeRF> atom "A String"
0
KeRF> atom 37
1
KeRF> atom -0.2
1
KeRF> atom 2015.03.31
1
KeRF> atom null
1
KeRF> atom [2, 5, 16]
0
KeRF> atom a: 45, b: 76
1
```

8.11 avg - Average

avg(x)

Calculate the arithmetic mean of the elements of a list x. Equivalent to (sum x)/count_nonnull x.

```
KeRF> avg 3 7 12.5 9
7.875
```

8.12 between - Between?

```
between(x, y)
```

Predicate which returns 1 if x is between the first two elements of the list y. Equivalent to $(x \ge y[0]) & (x \le y[1])$.

```
KeRF> between(2 5 17, 3 10)
[0, 1, 0]
```

Be careful- between will always fail if y is not a list or does not have the correct length:

```
KeRF> between(2 5 17, 3)
[0, 0, 0]

KeRF> 3[1]
NAN
```

8.13 btree - BTree

btree(x)

Equivalent to indexed(x).

8.14 bucketed - Bucket Values

```
bucketed(x, y)
```

Equivalent to floor (<<y) * x / count y.

8.15 car - Contents of Address Register

car(x)

Select the first element of the list x. Atomic types are unaffected by this operation. Equivalent to first(x). car is a reference to the Lisp primitive of the same name, which selected the first element of a pair.

```
KeRF> car 32 83 90
    32
KeRF> car 409
    409
KeRF> nil = car []
    1
```

8.16 cdr - Contents of Data Register

cdr(x)

Select all the elements of the list x except for the first. Atomic types are unaffected by this operation. Equivalent to drop(1, x). cdr is a reference to the Lisp primitive of the same name, which selected the second element of a pair.

```
KeRF> cdr 32 83 90

[83, 90]

KeRF> cdr 409

409
```

8.17 ceil - Ceiling

ceil(x)

Compute the smallest integer following a number x. Atomic.

```
KeRF> ceil -3.2 0.4 0.9 1.1 [-3, 1, 1, 2]
```

Taking the ceiling of a string or char converts it to uppercase:

```
KeRF> ceil "Hello, World!"
  "HELLO, WORLD!"
```

8.18 char - Cast to Char

char(x)

Cast a number or list x to a char or string, respectively.

```
KeRF> char 65
    "A"
KeRF> char 66.7
    "B"
KeRF> char 72 101 108 108 111 44 32 75 101 82 70 33
    "Hello, KeRF!"
```

8.19 close_socket - Close Socket

close_socket(x)

Given a socket handle as obtained with open_socket, close the connection. See Network I/O.

8.20 cos - Cosine

cos(x)

Calculate the cosine of x, expressed in radians. Atomic. The results of cos will always be floating point values.

```
KeRF> cos 3.14159 1 -20
[-1, 0.540302, 0.408082]
KeRF> acos cos 3.14159 1 -20
[3.14159, 1, 1.15044]
```

8.21 cosh - Hyperbolic Cosine

cosh(x)

Calculate the hyperbolic cosine of x, expressed in radians. Atomic. The results of cosh will always be floating point values.

```
KeRF> cosh 3.14159 1 -20
[11.5919, 1.54308, 2.42583e+08]
```

8.22 count - Count

count(x)

Determine the number of elements in x. Equivalent to len(x). Atomic elements have a count of 1.

```
KeRF> count 4 7 9
3
KeRF> count [4 7 9, 23 32]
2
KeRF> count 5
1
KeRF> count {a:23, b:45}
1
```

8.23 count_nonnull - Count Non-Nulls

count_nonnull(x)

Determine the number of elements in x which are not null. Equivalent to sum not isnull x.

```
KeRF> count_nonnull 1 2 3
3
KeRF> count_nonnull [nan, null, 45]
1
```

8.24 count_null - Count Nulls

count_null(x)

Determine the number of elements in x which are null. Equivalent to sum isnull x.

```
KeRF> count_null 1 2 3
0
KeRF> count_null [nan, null, 45]
2
```

8.25 descend - Descending Indices

descend(x)

For a list x, generate a list of indices into x in descending order of the values of x.

```
KeRF> t:5 2 3 1
  [5, 2, 3, 1]
KeRF> descend t
  [0, 2, 1, 3]
KeRF> t[descend t]
  [5, 3, 2, 1]
```

Strings are sorted in lexicographic order:

```
KeRF> descend ["Orange", "Apple", "Pear", "Aardvark", "A"]
[2, 0, 1, 3, 4]
```

When applied to a map, descend will sort the keys by their values and produce a list:

```
KeRF> ascend {"A":2, "B":9, "C":0}
["B", "A", "C"]
```

The symbol > is equivalent to descend when used as a unary operator:

```
KeRF> >5 2 3 1
[0, 2, 1, 3]
```

8.26 dir_ls - Directory Listing

```
dir_ls(path)
dir_ls(path, full)
```

List the files and directories at a filesystem path. If full is provided and truthy, list complete paths to the elements of the directory. Otherwise, list only the base names. See File I/O.

8.27 display - Display

display(x)

Print a display representation of data to standard output. See **General I/O**.

8.28 distinct - Distinct Values

distinct(x)

Select the first instance of each item in a list x. Atomic types are unaffected by this operation.

```
KeRF> distinct "BANANA"
    "BAN"
KeRF> distinct 2 3 3 5 3 4 5
    [2, 3, 5, 4]
```

The symbol % is equivalent to distinct when used as a unary operator:

```
KeRF> %"BANANA"
"BAN"
```

8.29 divide - Divide

```
divide(x, y)
```

Divide x by y. Fully atomic. The results of divide will always be floating point values.

```
KeRF> divide(3, 5)
    0.6
KeRF> divide(-1, 0)
    -inf
KeRF> divide(3, 2 4 5 0)
    [1.5, 0.75, 0.6, inf]
KeRF> divide(1 3 4 0, 9)
    [0.111111, 0.333333, 0.444444, 0.0]
KeRF> divide(10 5 3, 7 9 3)
    [1.42857, 0.555556, 1.0]
```

The symbol / is equivalent to divide when used as a binary operator:

```
KeRF> 10 5 3 / 7 9 3
[1.42857, 0.555556, 1.0]
```

8.30 dlload - Dynamic Library Load

```
dlload(filename, function, argcount)
```

Load a dynamic library function and return a KeRF function which can be invoked to call into it. filename is the name of the library, function is the name of the function and argcount is the number of arguments the function takes.

Let's look at a very simple of writing a C function which can be called from KeRF. Begin with the following saved as dynamic.c. All values passed into and out of dynamic libraries are KERF structures, as defined below.

To compile on OSX, invoke your system's C compiler as follows:

```
cc -m64 -dynamiclib dynamic.c -o example.dylib
```

Then, with the resulting example.dylib in the current directory, load it from KeRF:

```
KeRF> f: dlload("example.dylib", "foreign_function_example", 1)
  {OBJECT:foreign_function_example}
KeRF> f(42)
Hello from C! You gave me a 42.
```

To return a result from a dynamic library, you must malloc your own KERF structs and initialize the fields appropriately. KeRF will automatically transfer malloced foreign function return values into its own reference-counted memory pool. Here's a very simple C function which constructs a KeRF integer value:

8.31 dotp - Dot Product

```
dotp(x, y)
```

Calculate the dot product (or scalar product) of the vectors x and y. Equivalent to sum x*y.

```
KeRF> dotp(1 2 3, 1 2 5)
20
```

8.32 drop - Drop Elements

```
drop(x, y)
```

Remove x elements from the beginning of the list y. Atomic types are unaffected by this operation.

```
KeRF> drop(3, "My Hero")
   "Hero"
KeRF> drop(5, 9 2 0)
[]
KeRF> drop(3, 5)
5
```

The symbol $_$ is equivalent to drop when used as a binary operator:

```
KeRF> 3 _ "My Hero"
"Hero"
```

8.33 enlist - Enlist Element

enlist(x)

Wrap any element x in a list.

```
KeRF> enlist "A"
  ["A"]
KeRF> enlist 22 33
  [[22, 33]]
```

8.34 enum - Enumeration

enum(x)

Equivalent to hashed(x).

8.35 enumerate - Enumerate Items

enumerate(x)

If x is a number, generate a range of integers from 0 up to but not including x. Equivalent to til(x).

```
KeRF> enumerate 0
   INT[]
KeRF> enumerate 3
```

```
[0, 1, 2]
KeRF> enumerate 5.3
[0, 1, 2, 3, 4]
```

If x is a map, extract its keys.

```
KeRF> enumerate b:43, a:999
["b", "a"]
```

The symbol ^ is equivalent to enumerate when used as a unary operator:

```
KeRF> ^9
[0, 1, 2, 3, 4, 5, 6, 7, 8]
```

8.36 equal - Equal?

```
equal(x, y)
```

A predicate which returns 1 if x is equal to y. Equivalent to equals(x). Fully atomic.

```
KeRF> equal(5, 13)
     0
KeRF> equal(5, 5 13)
     [1, 0]
KeRF> equal(5 13, 5 13)
     [1, 1]
KeRF> equal(.1, .10000000000001)
     0
KeRF> equal(nan, nan)
     1
```

The symbols = and == are equivalent to equal when used as binary operators:

```
KeRF> 3 == 1 3 5
[0, 1, 0]
```

8.37 equals - Equals?

```
equals(x, y)
```

A predicate which returns 1 if x is equal to y. Equivalent to equal(x). Fully atomic.

8.38 erf - Error Function

erf(x)

Compute the Gauss error function of x. Atomic.

```
KeRF> erf -.5 -.2 0 .2 .3 1 2
[-0.5205, -0.222703, 0, 0.222703, 0.328627, 0.842701, 0.995322]
```

8.39 erfc - Complementary Error Function

erfc(x)

Compute the complementary Gauss error function of x. Equivalent to 1 - erf(x). Atomic.

```
KeRF> erfc -.5 -.2 0 .2 .3 1 2
[1.5205, 1.2227, 1, 0.777297, 0.671373, 0.157299, 0.00467773]
```

8.40 eval - Evaluate

eval(x)

Evaluate a string x as a KeRF expression. Partially atomic.

```
KeRF> a
KeRF> eval(["2+3", "a: 24", "a: 999"])
  [5, 24, 999]
KeRF> a
  999
```

8.41 except - Except

except(x, y)

Remove all the elements of y from x. Equivalent to x[?!x in y].

```
KeRF> except("ABCDDBEFB", "ADF")
   "BCBEB"
```

If x is atomic, the result will be enclosed in a list:

```
KeRF> except(2, 3 4)
[2]
```

8.42 exit - Exit

exit()
exit(x)

Exit the KeRF interpreter. If a number x is provided, use it as an exit code. Otherwise, exit with code 0 (successful).

```
KeRF> exit(1)
```

8.43 exp - Natural Exponential Function

```
exp(x)

exp(x, y)
```

Calculate e^x , the natural exponential function. If y is provided, calculate x^y . Fully atomic.

```
KeRF> exp 1 2 5
  [2.71828, 7.38906, 148.413]
KeRF> exp(2, 0 1 2)
  [1, 2, 4.0]
```

The symbol ** is equivalent to exp:

```
KeRF> **1 2 5
[2.71828, 7.38906, 148.413]
KeRF> 2**0 1 2
[1, 2, 4.0]
```

8.44 explode - Explode

```
explode(x, y)
```

Violently and suddenly split the list y at instances of x. To reverse this process, use implode.

```
KeRF> explode("e", "A dream deferred")
  ["A dr", "am d", "f", "rr", "d"]
KeRF> explode(0, 1 1 2 0 2 0 5)
  [[1, 1, 2], [2], [5]]
```

Note that explode does not search for subsequences. Splitting on a 1-length string is not the same as splitting on a character:

```
KeRF> explode("rat", "drat, that rat went splat.")
  ["drat, that rat went splat."]
KeRF> explode("e", "A dream deferred")
  ["A dream deferred"]
```

8.45 first - First

```
first(x)
first(x, y)
```

When provided with a single argument, select the first element of the list x. Atomic types are unaffected by this operation.

```
KeRF> first(43 812 99 23)
  43
KeRF> first(99)
  99
```

When provided with two arguments, select the first x elements of y, repeating elements of y as necessary. Equivalent to take (x, y).

```
KeRF> first(2, 43 812 99 23)
  [43, 812]
KeRF> first(8, 43 812 99 23)
  [43, 812, 99, 23, 43, 812, 99, 23]
```

8.46 flatten - Flatten

flatten(x)

Concatenate the elements of the list x. To join elements with a delimiter, use implode.

```
KeRF> flatten(["foo", "bar", "quux"])
   "foobarquux"
KeRF> flatten([2 3 4, 9 7 8, 14])
   [2, 3, 4, 9, 7, 8, 14]
```

Note that flatten only removes one level of nesting. To completely flatten an arbitrarily nested structure, combine it with converge:

```
KeRF> n: [[1,2],[3,4],[5,[6,7]]];
KeRF> flatten n
  [1, 2, 3, 4, 5, [6, 7]]
KeRF> flatten converge n
  [1, 2, 3, 4, 5, 6, 7]
```

8.47 float - Cast to Float

float(x)

Cast x to a float. Atomic.

```
KeRF> float 0 7 15
[0, 7, 15.0]
```

When applied to a string, parse it into a number:

```
KeRF> float "97"
97.0
```

8.48 floor - Floor

floor(x)

Compute the largest integer preceding a number x. Atomic.

```
KeRF> floor -3.2 0.4 0.9 1.1
  [-4, 0, 0, 1]
KeRF> int -3.2 0.4 0.9 1.1
  [-3, 0, 0, 1]
```

Taking the floor of a string or char converts it to lowercase:

```
KeRF> floor "Hello, World!"
   "hello, world!"
```

The symbol _ is equivalent to floor when used as a unary operator:

```
KeRF> _ 37.9 14.2 [37, 14]
```

8.49 greater - Greater Than?

```
greater(x, y)
```

A predicate which returns 1 if x is greater than y. Fully atomic.

```
KeRF> greater(1 2 3, 2)
  [0, 0, 1]
KeRF> greater([5], [[], [3], [2 9]])
  [0, 1, 0]
KeRF> greater("apple", ["a", "aa", "banana"])
  [1, 1, 0]
```

The symbol > is equivalent to greater when used as a binary operator:

```
KeRF> 3 4 7 > 1 9 0
[1, 0, 1]
```

8.50 greatereq - Greater or Equal?

```
greatereq(x, y)
```

A predicate which returns 1 if x is greater than or equal to y. Fully atomic.

```
KeRF> greatereq(1 2 3, 2)
  [0, 1, 1]
```

The symbol >= is equivalent to greatereq when used as a binary operator:

```
KeRF> 3 4 5 7 >= 1 9 5 0
[1, 0, 1, 1]
```

8.51 has_column - Table Has Column?

has_column(x, y)

A predicate which returns 1 if table x has a column with the key y.

```
KeRF> has_column({{a: 1 2 3; b: 4 2 1}}, "a")
    1
KeRF> has_column({{a: 1 2 3; b: 4 2 1}}, "fictional")
    0
```

8.52 has_key - Has Key?

has_key(x, y)

A predicate which returns 1 if a map x contains the key y.

```
KeRF> m: {alphonse: 1, betty: 3, oscar: 99};
KeRF> has_key(m, "alphonse")
   1
KeRF> has_key(m, "alphys")
   0
```

If x is a list, return 1 if y is a valid index into x:

If x is a table, equivalent to has_column(x, y).

8.53 hash - Hash

hash(x)

Equivalent to hashed(x).

8.54 hashed - Hashed

hashed(x)

Create a list containing the elements of x, with hashmap-backed local interning. Interning will minimize the storage consumed by values which occur frequently and permit much more efficient sorting.

```
KeRF> data: rand(10000, ["apple", "pear", "banana"]);
KeRF> write_to_path("a.data", data);
KeRF> write_to_path("b.data", #data);
KeRF> shell "wc -c a.data"
   [" 1048576 a.data"]
KeRF> shell "wc -c b.data"
   [" 262144 b.data"]
```

The symbol # is equivalent to hashed when used as a unary operator:

```
KeRF> #["a", "b", "a"]
#["a", "b", "a"]
```

8.55 ident - Identity

ident(x)

Unary identity function. Returns x unchanged.

```
KeRF> ident 42
42
```

The symbol: is equivalent to ident when used as a unary operator:

```
KeRF> :42
42
```

8.56 ifnull - If Null?

ifnull(x)

A predicate which returns 1 if x is null. Equivalent to isnull(x). Atomic.

```
KeRF> ifnull([(), nan, 2, -3.7, [], {a:5}])
[1, 1, 0, 0, [], {a:0}]
```

8.57 implode - Implode

```
implode(x, y)
```

Violently and suddenly join the elements of the list y intercalated with x. To reverse this process, use explode.

```
KeRF> implode("_and_", ["BIFF", "B00M", "P0W"])
    "BIFF_and_B00M_and_P0W"
KeRF> implode(23, 10 4 3 15)
    [10, 23, 4, 23, 3, 23, 15]
```

8.58 in - In?

in(x, y)

A predicate which returns 1 if each x is an element of y. Atomic over x.

```
KeRF> in(3, 8 7 3 2)
  [1]
KeRF> in(3 4, 8 7 3 2)
  [1, 0]
KeRF> in("a", "cassiopeia")
  [1]
```

8.59 index - Index

index(x)

Equivalent to indexed(x).

8.60 indexed - Indexed

indexed(x)

Create an indexed version of a list x. This constructs an associated B-Tree, permitting faster searches and range queries. Do not use indexed if you know the list must always be ascending. The command sort_debug can be used to determine whether KeRF thinks a list is already sorted.

```
KeRF> indexed 3 7 0 5 2
=[3, 7, 0, 5, 2]
```

The symbol = is equivalent to indexed when used as a unary operator:

```
KeRF> =3 2
=[3, 2]
```

8.61 int - Cast to Int

int(x)

Cast x to an int, truncating. Atomic.

```
KeRF> int 33.6 -12.5 4 nan
[33, -12, 4, NAN]
KeRF> floor 33.6 -12.5 4 nan
[33, -13, 4, NAN]
```

When applied to a string, parse it into an integer:

```
KeRF> int ["1337", "47.2", ""]
[1337, 47, 0]
```

8.62 intersect - Set Intersection

intersect(x, y)

Find unique items contained in both x and y. Equivalent to distinct(x) [which distinct(x) in y].

```
KeRF> intersect(4, 4 5 6)
  [4]
KeRF> intersect(3 4, 1 2 3 4 5 6)
  [3, 4]
KeRF> intersect("ABD", "BCBD")
  "BD"
```

8.63 isnull - Is Null?

isnull(x)

A predicate which returns 1 if x is null. Atomic.

```
KeRF> isnull([(), nan, 2, -3.7, [], {a:5}])
[1, 1, 0, 0, [], {a:0}]
```

8.64 join - Join

join(x, y)

Form a list by catenating x and y.

```
KeRF> join(2 3, 4 5)
  [2, 3, 4, 5]
KeRF> join(2 3, 4)
  [2, 3, 4]
```

```
KeRF> join(2 3, "ABC")
  [2, 3, `"A", `"B", `"C"]
KeRF> join({a:23, b:24}, {b:99})
  [{a:23, b:24}, {b:99}]
```

The symbol # is equivalent to join when used as a binary operator:

```
KeRF> 2 3 # 9
[2, 3, 9]
```

8.65 json_from_kerf - Convert KeRF to JSON

json_from_kerf(x)

Convert a KeRF data structure x into a JSON (IETF RFC-4627) string.

```
KeRF> json_from_kerf({a: 45, b: [1, 3, 5.0]})
   "{\"a\":45,\"b\":[1,3,5]}"
KeRF> json_from_kerf({{a: 1 2 3, b: 4 5 6}})
   "{\"a\":[1,2,3],\"b\":[4,5,6],\"is_json_table\":[1]}"
```

8.66 kerf_from_json - Convert JSON to KeRF

kerf_from_json(x)

Convert a JSON (IETF RFC-4627) string x into a KeRF data structure. Note that booleans become the numbers 1 and 0 during this conversion process. KeRF-generated JSON strings generally contain the metadata necessary to round-trip without information loss, but JSON strings produced by another program may not.

```
KeRF> kerf_from_json("[23, 45, 9]")
  [23, 45, 9]
KeRF> kerf_from_json("[true, false]")
  [1, 0]
KeRF> kerf_from_json("{\"a\":[1,2,3],\"b\":[4,5,6]}")
  a:[1, 2, 3], b:[4, 5, 6]
KeRF> kerf_from_json("{\"a\":[1,2,3],\"b\":[4,5,6],\"is_json_table\":[1]}")
  a b
  1 4
  2 5
  3 6
```

8.67 kerf_type - Type Code

kerf_type(x)

Obtain a numeric typecode from a KeRF value.

```
KeRF> kerf_type 45.0
3
```

Type	Example	kerf_type_name	kerf_type
Timestamp Vector	[2000.01.01]	stamp vector	-4
Float Vector	[0.1]	float vector	-3
Integer Vector	[1]	integer vector	-2
Character Vector	"A"	character vector	-1
Function	$\{[x] 1+x\}$	function	0
Character	` A	character	1
Integer	1	integer	2
Float	0.1	float	3
Timestamp	2000.01.01	stamp	4
Null	()	null	5
List	[]	list	6
Map	{a:1}	map	7
Enumeration	enum ["a"]	enum	8
Index	index [1,2]	sort	9
Table	$\{\{a:1\}\}$	table	10
Atlas	atlas $\{a:1\}$	atlas	11

KeRF types

8.68 kerf_type_name - Type Name

kerf_type_name(x)

Obtain a human-readable type name string from a KeRF value. See $\texttt{kerf_type}.$

```
KeRF> kerf_type_name "Text"
   "character vector"
```

8.69 last - Last

```
last(x)
last(x, y)
```

When provided with a single argument, select the last element of the list x. Atomic types are unaffected by this operation.

```
KeRF> last(43 812 99 23)
23
KeRF> last(99)
99
```

When provided with two arguments, select the last x elements of y, repeating elements of y as necessary. Equivalent to take (-x, y).

```
KeRF> last(2, 43 812 99 23)
  [99, 23]
KeRF> last(7, 43 812 99 23)
  [812, 99, 23, 43, 812, 99, 23]
```

8.70 left_join - Left Join

```
left_join(x, y, z)
```

Peform a left join of the tables x and y on the column z. See Joins.

8.71 len - Length

len(x)

Determine the number of elements in x. Equivalent to count(x). Atomic elements have a count of 1.

```
KeRF> len 4 7 9
3
KeRF> len [4 7 9, 23 32]
2
KeRF> len 5
1
KeRF> len {a:23, b:45}
1
```

8.72 less - Less Than?

less(x, y)

A predicate which returns 1 if x is less than y. Fully atomic.

```
KeRF> less(1 2 3, 2)
  [1, 0, 0]
KeRF> less([5], [[], [3], [2 9]])
  [1, 0, 1]
KeRF> less("apple", ["a", "aa", "banana"])
  [0, 0, 1]
```

The symbol < is equivalent to less when used as a binary operator:

```
KeRF> 3 4 7 < 1 9 0
[0, 1, 0]
```

8.73 lesseq - Less or Equal?

lesseq(x, y)

A predicate which returns 1 if x is less than or equal to x. Fully atomic.

```
KeRF> lesseq(1 2 3, 2)
  [1, 1, 0]
KeRF> lesseq([5], [[], [3], [5], [2 9]])
  [1, 0, 0, 1]
KeRF> lesseq("apple", ["a", "aa", "apple", "banana"])
  [0, 0, 1, 1]
```

The symbol <= is equivalent to lesseq when used as a binary operator:

```
KeRF> 3 4 1 7 <= 1 9 1 0
[0, 1, 1, 0]
```

8.74 lg - Base 2 Logarithm

lg(x)

Calculate $\log_2(x)$. Equivalent to $\log(2, x)$. Atomic.

```
KeRF> lg 128 512 37
[7, 9, 5.20945]
```

8.75 lines - Lines From File

```
lines(filename)
lines(filename, n)
```

Load lines from filename into a list of strings. If n is present, limit loading to n lines. See File I/O.

8.76 ln - Natural Logarithm

ln(x)

Calculate $\log_e(x)$. Atomic.

```
KeRF> ln 2 3 10 37
[0.693147, 1.09861, 2.30259, 3.61092]
```

8.77 load - Load Source

load(filename)

Load and run KeRF source from a file. Given an example file:

```
// comment
a: 7+range 10
b: range 10
a * b
```

Loading the file from the Repl:

```
KeRF> load("manual/example.kerf")
KeRF> a
  [7, 8, 9, 10, 11, 12, 13, 14, 15, 16]
KeRF> b
  [0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

Note that the value of the raw expression a * b is not printed when you load a file. If this is desired, use display in the script.

8.78 log - Logarithm

```
log(x)
log(x, y)
```

Calculate the base x logarithm of y. If only one argument is provided, log(10, x) is assumed. Fully atomic.

```
KeRF> log 3 8 10 16 100
  [0.477121, 0.90309, 1, 1.20412, 2.0]
  KeRF> log(2, 3 8 10 16 100)
  [1.58496, 3, 3.32193, 4, 6.64386]
  KeRF> log(2 3 4, 8)
  [3, 1.89279, 1.5]
```

8.79 lsq - Least Squares Solution

lsq(A, B)

Solve Ax = B for x, where A is a matrix and B is a matrix or vector.

```
KeRF> lsq([1 2;4 4], [3 4])
  [[1, 0.5]]
KeRF> lsq([0 .5;2 0], [0 1;1 0])
  [[2, 0.0],
  [0, 0.5]]
```

The symbol \ is equivalent to lsq when used as a binary operator:

```
KeRF> [0 .5;2 0]\[0 1;1 0]
[[2, 0.0],
[0, 0.5]]
```

8.80 map - Make Map

```
map(x, y)
```

Make a map from a list of keys x and a list of values y. These lists must be the same length.

```
KeRF> map("ABC", 44 18 790)
{`"A":44, `"B":18, `"C":790}
```

The symbol! is equivalent to map when used as a binary operator:

```
KeRF> "ABC" ! 44 18 790 {\"A":44, \"B":18, \"C":790}
```

8.81 match - Match?

```
match(x, y)
```

A predicate which returns 1 if x is identical to y. While equals compares atoms, match is not atomic and compares entire values.

```
KeRF> match(5, 3 5 7)
0
KeRF> match(3 5 7, 3 5 7)
1
```

The symbol $\tilde{\ }$ is equivalent to match when used as a binary operator:

```
KeRF> 3 5 7 ~ 3 5 7 1
```

8.82 mavg - Moving Average

```
mavg(x, y)
```

For a series of sliding windows of size x ending at each element of the list y, find the arithmetic mean of valid (not nan and in range of the list) elements. Equivalent to msum(x, y)/mcount(x, y).

```
KeRF> mavg(3, 1 2 4 2 1 nan 0 4 6 7)
[1, 1.5, 2.33333, 2.66667, 2.33333, 1.5, 0.5, 2, 3.33333, 5.66667]
```

8.83 max - Maximum

max(x)

Find the maximum element of x. Roughly equivalent to last sort, but much more efficient.

```
KeRF> max 7 0 15 -1 8
   15
KeRF> max 0 -inf -5 nan inf
   inf
```

8.84 maxes - Maximums

maxes(x, y)

Find the maximum of x and y. Fully atomic.

```
KeRF> maxes(1 3 7 2 0 1, -4 3 20 1 9 4)
  [1, 3, 20, 2, 9, 4]
KeRF> maxes(8, -4 3 20 1 9 4)
  [8, 8, 20, 8, 9, 8]
```

The symbol | is equivalent to maxes when used as a binary operator:

```
KeRF> -4 3 20 1 9 4 | 15
[15, 15, 20, 15, 15, 15]
```

8.85 mcount - Moving Count

```
mcount(x, y)
```

For a series of sliding windows of size x ending at each element of the list y, count the number of valid (not nan and in range of the list) elements. Equivalent to msum(x, not isnull y).

```
KeRF> mcount(3, 1 2 3 nan 4 5 nan nan nan)
[1, 2, 3, 2, 2, 2, 1, 0]
```

8.86 median - Median

median(x)

Select the median of a list of numbers x:

```
KeRF> median 1 3 19 7 4 2
3.5
```

8.87 meta_table - Meta Table

meta_table(x)

Produce a table containing debugging metadata about some some table x:

```
      KeRF> meta_table {{a: 1 2 3, b: 3.0 17 4}}

      column type type_name is_ascending is_disk

      a -2 integer vector b -3 float vector 0 0
```

8.88 min - Minimum

min(x)

Find the minimum element of x. Roughly equivalent to first sort, but much more efficient.

```
KeRF> min 7 0 15 -1 8
   -1
KeRF> min 0 -inf -5 nan inf
   -inf
```

8.89 mins - Minimums

mins(x, y)

Find the minimum of x and y. Fully atomic.

```
KeRF> mins(1 3 7 2 0 1, -4 3 20 1 9 4)
  [-4, 3, 7, 1, 0, 1]
KeRF> mins(8, -4 3 20 1 9 4)
  [-4, 3, 8, 1, 8, 4]
```

The symbol & is equivalent to mins when used as a binary operator:

```
KeRF> -4 3 20 1 9 4 & 15
[-4, 3, 15, 1, 9, 4]
```

8.90 minus - Minus

```
minus(x, y)
```

Calculate the difference of x and y. Fully atomic.

```
KeRF> minus(3, 5)
    -2
KeRF> minus(3, 9 15 -7)
    [-6, -12, 10]
KeRF> minus(9 15 -7, 3)
    [6, 12, -10]
KeRF> minus(9 15 -7, 1 3 5)
    [8, 12, -12]
```

The symbol - is equivalent to minus when used as a binary operator:

```
KeRF> 2 4 3 - 9
[-7, -5, -6]
```

8.91 minv - Matrix Inverse

minv(x)

Calculate the inverse of a matrix x.

```
KeRF> minv([1 2;3 4])
  [[-2, 1],
  [1.5, -0.5]]
```

8.92 mmax - Moving Maximum

```
mmax(x, y)
```

For a series of sliding windows of size x ending at each element of the list y, find the maximum element. Equivalent to (x-1) or mapback converge y.

```
KeRF> mmax(3, 0 1 0 2 0 1 0)
[0, 1, 1, 2, 2, 2, 1]
```

8.93 mmin - Moving Minimum

```
mmin(x, y)
```

For a series of sliding windows of size x ending at each element of the list y, find the minimum element. Equivalent to (x-1) and mapback converge y.

```
KeRF> mmin(3, 4 0 3 0 2 0 4 5 6)
[4, 0, 0, 0, 0, 0, 0, 4]
```

8.94 mmul - Matrix Multiply

```
mmul(x, y)
```

Multiply the matrix or vector x by the matrix or vector y. Equivalent to x dotp mapleft y.

```
KeRF> mmul([1 2;3 4], [5 6])
  [[15, 18],
    [35, 42]]
KeRF> mmul([1 2;3 4], [0 1;1 0])
  [[2, 1],
    [4, 3]]
```

8.95 mod - Modulus

```
mod(x, y)
```

Calculate x modulo y. Equivalent to x - y * floor(x/y). Left-atomic.

```
KeRF> mod(0 1 2 3 4 5 6 7, 3)
  [0, 1, 2, 0, 1, 2, 0, 1]
KeRF> mod(-4 -3 -2 -1 0 1 2, 2)
  [0, 1, 0, 1, 0, 1, 0]
```

The symbol % is equivalent to mod when used as a binary operator:

```
KeRF> 0 1 2 3 4 5 6 7 % 3
[0, 1, 2, 0, 1, 2, 0, 1]
```

8.96 msum - Moving Sum

```
msum(x, y)
```

Calculate a series of sums of each element in a list y and up to the x previous values, ignoring nans and nonexistent values.

```
KeRF> msum(2, 10 20 30 40)
  [10, 30, 50, 70]
KeRF> msum(2, 1 2 2 nan 1 2)
  [1, 3, 4, 2, 1, 3.0]
KeRF> msum(3, 10 10 14 10 25 10 Nan 10)
  [10, 20, 34, 34, 49, 45, 35, 20.0]
```

msum(1, y) can be used to remove nan from data:

```
KeRF> msum(1, 4 2 1 nan 2)
[4, 2, 1, 0, 2.0]
```

8.97 negate - Negate

negate(x)

Reverse the sign of a number x. Equivalent to -1 * x. Atomic.

```
KeRF> negate 2 4 -77
[-2, -4, 77]
```

The symbol - is equivalent to negate when used as a binary operator:

```
KeRF> -(2 4 -77)
[-2, -4, 77]
```

8.98 negative - Negative

negative(x)

Equivalent to negate(x).

8.99 not - Logical Not

not(x)

Calculate the logical NOT of x. Atomic.

```
KeRF> not(1 0)
  [0, 1]
KeRF> not([0, -4, 9, nan, []])
  [1, 0, 0, 0, []]
```

The symbol! is equivalent to not when used as a unary operator:

```
KeRF> !1 0 8
[0, 1, 0]
```

8.100 noteq - Not Equal?

noteq(x, y)

A predicate which returns 1 if x is not equal to y. Equivalent to not equals(x). Fully atomic.

```
KeRF> noteq(5, 13)
   1
KeRF> noteq(5, 5 13)
   [0, 1]
KeRF> noteq(5 13, 5 13)
   [0, 0]
KeRF> noteq(.1, .100000000000001)
   1
KeRF> noteq(nan, nan)
   0
```

The symbols != and <> are equivalent to noteq when used as binary operators:

```
KeRF> 3 != 1 3 5
[1, 0, 1]
```

8.101 now - Current DateTime

now()

Return a stamp containing the current date and time in UTC.

```
KeRF> now()
2015.10.31T21:14:09.018
```

8.102 now_date - Current Date

now_date()

Return a stamp containing the current date only in UTC.

```
KeRF> now_date()
2015.10.31
```

8.103 now_time - Current Time

now_time()

Return a stamp containing the current time only in UTC.

```
KeRF> now_time()
21:14:09.018
```

8.104 open_socket - Open Socket

```
open_socket(host, port)
```

Establish a connection to a remote KeRF instance at hostname host and listening on port and return a connection handle. Both host and port must be strings. See **Network I/O**.

8.105 open_table - Open Table

```
open_table(filename)
```

Load a serialized table from the binary file filename. See File I/O.

8.106 or - Logical OR

```
or(x, y)
```

Calculate the logical OR of x and y. This operation is equivalent to the primitive function max. Fully atomic.

```
KeRF> or(1 1 0 0, 1 0 1 0)
  [1, 1, 1, 0]
KeRF> or(1 2 3 4, 0 -4 9 0)
  [1, 2, 9, 4]
```

The symbol | is equivalent to or when used as a binary operator:

```
KeRF> 1 1 0 0 | 1 0 1 0 [1, 1, 1, 0]
```

8.107 order - Order

order(x)

Generate a list of indices showing the relative ascending order of items in the list x. Equivalent to <<x.

```
KeRF> order "ABCEDF"
[0, 1, 2, 4, 3, 5]
KeRF> order 2 4 1 9
[1, 2, 0, 3]
KeRF> <2 4 1 9
[2, 0, 1, 3]
KeRF> <<2 4 1 9
[1, 2, 0, 3]
```

8.108 out - Output

out(x)

Print a string x to standard output. See **General I/O**.

8.109 part - Partition

part(x)

Produce a map from unique elements of a list x to lists of the indices at which these elements could originally be found.

```
KeRF> part 3 5 7 7 5
   {3:[0], 5:[1, 4], 7:[2, 3]}
KeRF> part ["apple", "frog", "kumquat"]
   {apple:[0], frog:[1, 2], kumquat:[3]}
```

part does not affect atomic types:

```
KeRF> part {a: 23 45, b: 9}
    {a:[23, 45], b:9}
KeRF> part 23
    23
```

The symbol & is equivalent to part when used as a unary operator:

```
KeRF> &2 2 1 2
{2:[0, 1, 3], 1:[2]}
```

8.110 plus - Plus

plus(x, y)

Equivalent to add.

8.111 pow - Exponentiation

```
pow(x)
pow(x, y)
```

Equivalent to exp.

8.112 rand - Random Numbers

```
rand()
rand(x)
rand(x, y)
```

Generate a random integer vector of x integers from 0 up to but not including y. If x is negative, draw numbers in the given range without replacement. That is, drawn numbers will be unique.

```
KeRF> rand(10, 3)
  [0, 2, 1, 2, 1, 2, 1, 2, 0, 2]
KeRF> rand(-5, 10)
  [3, 9, 4, 0, 8]
```

If y is a list, select random elements from y. As above, a negative x produces draws without replacement:

```
KeRF> rand(6, "ABC")
  "CBCBBA"
KeRF> rand(-7, "ABCDEFG")
  "DAGBFCE"
```

If y is not provided, generate a single random integer from 0 up to but not including x. As above, if x is a list, draw a single random element.

```
KeRF> rand(10)
   1
KeRF> rand(10)
   8
KeRF> rand(10)
   7
KeRF> rand("ABCDE")
   ""B"
```

If rand is given no arguments, generate a single random float from 0 up to but not including 1.

```
KeRF> rand()
  0.389022
```

The symbol? is equivalent to rand when used as a binary operator:

```
KeRF> 5?2
[0, 0, 1, 0, 0]
```

8.113 range - Range

```
range(x)
range(x, y)
range(x, y, z)
```

If range is provided with one argument, generate a vector of integers from 0 up to but not including x:

```
KeRF> range 5
[0, 1, 2, 3, 4]
```

If range is provided with two arguments, generate a vector of numbers from x up to but not including y, spaced 1 apart:

```
KeRF> range(10, 15)
  [10, 11, 12, 13, 14]
KeRF> range(10.5, 16.5)
  [10.5, 11.5, 12.5, 13.5, 14.5, 15.5]
```

If range is provided with three arguments, generate a vector of numbers from **x** up to but not including **y**, spaced **z** apart:

```
KeRF> range(1, 3, .3)
[1, 1.3, 1.6, 1.9, 2.2, 2.5, 2.8]
```

8.114 read_from_path - Read From Path

read_from_path(filename)

Load a serialized KeRF data structure from the binary file filename. See File I/O.

8.115 read_table_from_csv - Read Table From CSV File

```
read_table_from_csv(filename, fields, n)
```

Load a Comma-Separated Value file into a table. fields is a string which indicates the expected datatype of each column in the CSV file- see read_table_from_delimited_file for the supported column types and their symbols. n indicates how many rows of the file are treated as column headers- generally 0 or 1.

Equivalent to read_table_from_delimited_file(",", filename, fields, n).

8.116 read table from delimited file - Read Table From Delimited File

```
read_table_from_delimited_file(delimiter, filename, fields, n)
```

Load the contents of a text file with rows separated by newlines and fields separated by some character delimiter into a table. fields is a string which indicates the expected datatype of each column. n indicates how many rows of the file are treated as column headers- generally 0 or 1. Given a file like the following:

```
Language&Lines&Runtime
C&271&0.101
Java&89&0.34
Python&62&3.79
```

Symbol	Datatype
I	Integer
F	Float
S	String
E	Enumerated String
G	IETF RFC-4122 UUID
N	IP address as parsed by inet_pton()
Z	Custom Datetime. See .Parse.strptime_format
Z	Custom Times. See .Parse.strptime_format2
*	Skipped field

Symbols accepted as part of fields

KeRF> read_table_from_delimited_file("&", "code.txt", "SIF", 1)
Language Lines Runtime

C 271 0.101
Java 89 0.34
Python 62 3.79

8.117 read_table_from_fixed_file - Read Table From Fixed-Width File

read_table_from_fixed_file(filename, attributes)

Load the contents of a text file with fixed-width columns. The map attributes specifies the details of the format:

Key	Type	Optional	Description
fields	String	No	As in read_table_from_delimited_file.
widths	Integer Vector	No	The width of each column in characters.
line_limit	Integer	Yes	The maximum number of rows to load.
titles	List of String	Yes	Key for each column in the resulting table.
header_rows	Integer	Yes	How many rows are treated as column headers.
newline_separated	Boolean	Yes	if false, do not expect newlines separating rows.

Settings described in attributes

Symbol	Datatype
Y	NYSE TAQ symbol
Q	NYSE TAQ time format (HHMMSSXXX)

Additional symbols accepted as part of fields in fixed-width files

Given a file like this list of ingredients for my famous pizza dough:

Eggs	2.0 -
	5.0 cups
Honey	2.0 tbs
Water	2.0 cups

```
Olive Oil 2.0 tbsp
Yeast 1.0 tbsp
```

```
KeRF> fmt: { fields: "SFS", widths: [10, 4, 5], titles: ["Ingredient", "Amount", "Unit"] };
KeRF> read table from fixed file("dough.txt", fmt)
 Ingredient | Amount | Unit
               2.0
       Eggs
               5.0 cups
      Flour
               2.0 tbsp
      Honey
      Water
               2.0
                    cups
               2.0 tbsp
  Olive Oil
               1.0|tbsp
      Yeast
```

8.118 read_table_from_tsv - Read Table From TSV File

read_table_from_tsv(filename, fields, n)

Load a Tab-Separated Value file into a table. fields is a string which indicates the expected datatype of each column in the TSV file- see read_table_from_delimited_file for the supported column types and their symbols. n indicates how many rows of the file are treated as column headers- generally 0 or 1.

Equivalent to read_table_from_delimited_file("\t", filename, fields, n).

8.119 rep - Output Representation

rep(x)

Convert a value x into a printable string representation. If you only wish to convert the atoms of x into strings, use string.

```
KeRF> rep 45
  "45"
KeRF> rep 2 5 3
  "[2, 5, 3]"
KeRF> rep {a:4}
  "{a:4}"
KeRF> rep "Some text"
  "\"Some text\""
```

8.120 repeat - Repeat

repeat(x, y)

Create a list containing x copies of y. Equivalent to x take enlist y.

```
KeRF> repeat(2, 5)
  [5, 5]
KeRF> repeat(4, "AB")
  ["AB", "AB", "AB", "AB"]
KeRF> repeat(0, "AB")
```

```
[]
KeRF> repeat(-3, "AB")
[]
```

8.121 reserved - Reserved Names

reserved()

Print and return an unsorted list of KeRF's reserved names, including reserved literals such as true.

8.122 reverse - Reverse

reverse(x)

Reverse the order of the elements of the list x. Atomic types are unaffected by this operation.

```
KeRF> reverse 23 78 94
  [94, 78, 23]
KeRF> reverse "backwards"
  "sdrawkcab"
KeRF> reverse 5
  5
KeRF> reverse {a: 23 56, b:0 1}
  a:[23, 56], b:[0, 1]
```

The symbol / is equivalent to reverse when used as a unary operator:

```
KeRF> /"example text"
  "txet elpmaxe"
```

8.123 rsum - Running Sum

rsum(x)

Calculate a running sum of the elements of the list x, from left to right. nans are ignored.

```
KeRF> rsum 1
1
KeRF> rsum 1 2
[1, 3]
KeRF> rsum 1 2 5
[1, 3, 8]
KeRF> rsum 1 2 5 7 8
[1, 3, 8, 15, 23]
KeRF> rsum 1 2 3 nan 4
[1, 3, 6, 6, 10.0]
KeRF> rsum []
[]
```

8.124 run - Run

run(filename)

Load and run KeRF source from a file. Equivalent to load(filename).

8.125 search - Search

```
search(x, y)
```

Look for x in y. If found, return the index. If not found, return NAN:

```
KeRF> search(3, 0 3 17 30)
   1
KeRF> search(30, 0 3 17 30)
   3
KeRF> search(15, 0 3 17 30)
   NAN
KeRF> search("F", "AEIOU")
   NAN
```

8.126 seed_prng - Set random seed

```
seed_prng(x)
```

Sets random number generator seed to x.

8.127 send_async - Send Asynchronous

```
send_async(x, y)
```

Given a connection handle x, as obtained with open_socket, send a string y to a remote KeRF instance and do not wait for a reply. See **Network I/O**.

8.128 send_sync - Send Synchronous

```
send_sync(x, y)
```

Given a connection handle x, as obtained with open_socket, send a string y to a remote KeRF instance, waiting for a reply. See **Network I/O**.

8.129 setminus - Set Disjunction

```
setminus(x, y)
```

Equivalent to except(x, y).

8.130 shell - Shell Command

```
shell(x)
```

Execute a string x containing a shell command as if from /bin/sh -c x. See General I/O.

8.131 shift - Shift

```
shift(x, y)
shift(x, y, z)
```

Offset y by x positions, filling shifted-in positions with z.

```
KeRF> shift(4, 1 2 3 4 5 6 7, 999)
  [999, 999, 999, 1, 2, 3]
KeRF> shift(-1, 1 2 3 4 5 6 7, 999)
  [2, 3, 4, 5, 6, 7, 999]
```

If z is not provided, use a type-appropriate null value as generated by type_null.

```
KeRF> shift(3, "ABCDE")
   " AB"
KeRF> shift(-3, "ABCDE")
   "DE "
KeRF> shift(2, 1 2 3 4)
   [NAN, NAN, 1, 2]
KeRF> shift(2, 1.0 2.0 3.0 4.0)
   [nan, nan, 1, 2.0]
```

8.132 shuffle - Shuffle

shuffle(x)

Randomly permute the elements of the list x. Equivalent to rand(-len(x), x).

```
KeRF> shuffle "APPLE"
   "PAEPL"
KeRF> shuffle "APPLE"
   "LEAPP"
KeRF> shuffle "APPLE"
   "LEPAP"
```

8.133 sin - Sine

sin(x)

Calculate the sine of x, expressed in radians. Atomic. The results of sin will always be floating point values.

```
KeRF> sin 3.14159 1 -20
  [2.65359e-06, 0.841471, -0.912945]
KeRF> asin sin 3.14159 1 -20
  [2.65359e-06, 1, -1.15044]
```

8.134 sinh - Hyperbolic Sine

sinh(x)

Calculate the hyperbolic sine of x, expressed in radians. Atomic. The results of sinh will always be floating point values.

```
KeRF> sinh 3.14159 1 -20
[11.5487, 1.1752, -2.42583e+08]
```

8.135 sleep - Sleep

sleep(x)

Delay for at least x milliseconds and then return x.

8.136 sort - Sort

sort(x)

Sort the elements of the list x in ascending order. Equivalent to x[ascend x].

```
KeRF> sort "ALPHABETICAL"

"AAABCEHILLPT"

KeRF> sort 27 18 4 9

[4, 9, 18, 27]

KeRF> sort unique "how razorback jumping frogs can level six piqued gymnasts"

" abcdefghijklmnopqrstuvwxyz"
```

8.137 sort_debug - Sort Debug

sort_debug(x)

Return a map containing debugging information about the list or table x which is relevant to the performance and internal datapaths of searching and sorting.

```
KeRF> sort_debug range(4)
  {attr_sorted:1, is_array:1, is_enum:0, is_actually_sorted_array:1, is_index:0,
    is_index_working:0, is_table:0, is_table_sorted:0}

KeRF> sort_debug "ACED"
  {attr_sorted:0, is_array:1, is_enum:0, is_actually_sorted_array:0, is_index:0,
    is_index_working:0, is_table:0, is_table_sorted:0}

KeRF> sort_debug 27
  {attr_sorted:1, is_array:0, is_enum:0, is_actually_sorted_array:0, is_index:0,
    is_index_working:0, is_table:0, is_table_sorted:0}

KeRF> sort_debug {{a: 4 2 1}}
  {attr_sorted:0, is_array:0, is_enum:0, is_actually_sorted_array:0, is_index:0,
    is_index_working:0, is_table:1, is_table_sorted:0}
```

8.138 split - Split List

```
split(x, y)
```

Subdivide the list x at the index/indices given by y. Equivalent to x[xvals part rsum (xkeys y) in x].

```
KeRF> split("SomeWordsTogether", 4 9)
    ["Some", "Words", "Together"]
KeRF> "ABCDEF" split 3
    ["ABC", "DEF"]
KeRF> split(11 22 33 44 55, 0 1 3 5)
    [[11], [22, 33], [44, 55]]
```

8.139 sqrt - Square Root

sqrt(x)

Calculate the square root of x. Atomic.

```
KeRF> sqrt 2 25 100
[1.41421, 5, 10.0]
```

8.140 stamp_diff - Timestamp Difference

```
stamp_diff(x, y)
```

Calculate the difference between the timestamps x and y in nanoseconds.

```
KeRF> t: now(); sleep(10); stamp_diff(now(), t)
    10302000
KeRF> t: now(); sleep(10); stamp_diff(t, now())
    -10874000
```

8.141 std - Standard Deviation

std(x)

Calculate the standard deviation of the elements of the list x. Equivalent to sqrt var x.

```
KeRF> std 4 7 19 2 0 -2
6.87992
KeRF> std {a: 4 1 0}
{a:1.69967}
```

8.142 string - Cast to String

string(x)

Convert the value x to a string. Atomic. If you wish to recursively convert an entire data structure to a string, use rep.

```
KeRF> string 990
   "990"
KeRF> string 15 9 10
   ["15", "9", "10"]
KeRF> string {a:4 5}
   {a:["4", "5"]}
```

8.143 subtract - Subtract

```
subtract(x, y)
```

Calculate the difference of x and y. Fully atomic. Equivalent to minus(x, y).

8.144 sum - Sum

sum(x)

Calculate the sum of the elements of the list x.

```
KeRF> sum 4 3 9
16
KeRF> sum 5
5
KeRF> sum []
0
```

8.145 tables - Tables

tables()

Generate a list of the names of all currently loaded tables.

```
KeRF> tables()
  []
KeRF> t: {{a: 1 2 3, b: 4 5 6}};
KeRF> tables()
  ["t"]
```

8.146 take - Take

take(x, y)

Create a list containing the first x elements of y, looping y as necessary. If x is negative, take backwards from the last to the first. Equivalent to first(x, y).

```
KeRF> take(3, `"A")
   "AAA"
KeRF> take(2, range(5))
   [0, 1]
KeRF> take(8, range(5))
   [0, 1, 2, 3, 4, 0, 1, 2]
KeRF> take(-3, range(5))
   [2, 3, 4]
```

The symbol ^ is equivalent to take when used as a binary operator:

```
KeRF> 3^"ABCDE"
"ABC
```

8.147 tan - Tangent

tan(x)

Calculate the tangent of x, expressed in radians. Atomic. The results of tan will always be floating point values.

```
KeRF> tan 0.5 -0.2 1 4
  [0.546302, -0.20271, 1.55741, 1.15782]
KeRF> atan(tan 0.5 -0.2 1 4)
  [0.5, -0.2, 1, 0.858407]
```

8.148 tanh - Hyperbolic Tangent

tanh(x)

Calculate the hyperbolic tangent of x, expressed in radians. Atomic. The results of tanh will always be floating point values.

```
KeRF> tanh 3.14159 1 -20 [0.996272, 0.761594, -1.0]
```

8.149 times - Multiplication

times(x, y)

Calculate the product of x and y. Fully atomic.

```
KeRF> times(3, 5)
   15
KeRF> times(1 2 3, 5)
   [5, 10, 15]
KeRF> times(3, 5 8 9)
   [15, 24, 27]
KeRF> times(10 15 3, 8 2 4)
   [80, 30, 12]
```

The symbol * is equivalent to times when used as a binary operator:

```
KeRF> 1 2 3*2
[2, 4, 6]
```

8.150 timing - Timing

timing(x)

If x is truthy, enable timing. Otherwise, disable it. Returns a boolean timing status. When timing is active, all operations will print their approximate runtime in milliseconds after completing.

```
KeRF> timing(1)
   1
KeRF> sum range exp(2, 24)
   140737479966720
```

```
203 ms
KeRF> timing(0)
0
```

8.151 tolower - To Lowercase

tolower(x)

Convert a string x to lowercase. Equivalent to floor(x).

8.152 toupper - To Uppercase

toupper(x)

Convert a string x to uppercase. Equivalent to ceil(x).

8.153 transpose - Transpose

transpose(x)

Take the transpose (flip the x and y axes) of a matrix x. Has no effect on atoms or lists of atoms.

```
KeRF> transpose [1 2 3, 4 5 6, 7 8 9]
  [[1, 4, 7],
  [2, 5, 8],
  [3, 6, 9]]
KeRF> transpose 1 2 3
  [1, 2, 3]
```

Atoms will "spread" as needed to produce a rectangular matrix if the list contains any sublists:

```
KeRF> transpose [2, 3 4 5, 6]
  [[2, 3, 6],
  [2, 4, 6],
  [2, 5, 6]]
```

The symbol + is equivalent to transpose when used as a unary operator:

```
KeRF> +[1 2, 3 4]
  [[1, 3],
  [2, 4]]
```

8.154 trim - Trim

trim(x)

Remove leading and trailing whitespace from strings. Atomic.

```
KeRF> trim(" some text ")
   "some text"
KeRF> trim [" some text ", " another", "\tab\t"]
   ["some text", "another", "ab"]
```

8.155 type_null - Type Null

type_null(x)

Generate the equivalent type-specific null value for \mathbf{x} .

```
KeRF> type_null("ABC")
    ""

KeRF> type_null(1.0)
    nan

KeRF> type_null(1)
    NAN

KeRF> type_null(now())
    00:00:00.000
```

8.156 uneval - Uneval

uneval(x)

Equivalent to json_from_kerf(x).

8.157 union - Set Union

union(x, y)

Construct an unsorted list of the unique elements in either x or y. Equivalent to distinct join(x, y).

```
KeRF> union(2, 4 5)
  [2, 4, 5]
KeRF> union([], 2)
  [2]
KeRF> union(2 3 4, 1 3 9)
  [2, 3, 4, 1, 9]
```

8.158 unique - Unique Elements

unique(x)

Equivalent to distinct(x).

8.159 var - Variance

var(x)

Calculate the variance of the elements of a list x. Equivalent to (sum (x - avg x)**2)/count_nonnull x.

```
KeRF> var []
   nan
KeRF> var 4 3 8 2
   5.1875
KeRF> sqrt var 4 3 8 2
   2.27761
```

8.160 which - Which

which(x)

For each index i of the list x, produce x[i] copies of i:

```
KeRF> which 1 2 1 4
  [0, 1, 1, 2, 3, 3, 3, 3]
KeRF> which 1 2 3
  [0, 1, 1, 2, 2, 2]
KeRF> which 1 1 1
  [0, 1, 2]
```

This operation is most often used to retrieve a list of the indices of nonzero elements of a boolean vector:

```
KeRF> which 0 0 1 0 1 1 0 1 [2, 4, 5, 7]
```

The symbol? is equivalent to which when used as a binary operator:

```
KeRF> ?0 0 1 0 1 1 0 1 [2, 4, 5, 7]
```

8.161 write_csv_from_table - Write CSV From Table

write_csv_from_table(filename, table)

Write table to disk as a Comma-Separated Value file called filename. Equivalent to write_delimited_file_from_table(",", filename, table).

8.162 write_delimited_file_from_table - Write Delimited File From Table

write_delimited_file_from_table(delimiter, filename, table)

Write table to disk as filename using newlines to separate rows and delimiter to separate columns. The file will be written with a header row corresponding to the keys of the columns of table. Returns the number of bytes written to the file.

```
KeRF> t: {{a: 1 2 3, b:["one", "two", "three"]}};
KeRF> write_delimited_file_from_table("|", "example.psv", t)
   23
KeRF> shell("wc -c example.psv")
   [" 23 example.psv"]
KeRF> shell("cat example.psv")
   ["a|b", "1|one", "2|two", "3|three"]
```

8.163 write_text - Write Text

write_text(filename, x)

Write the value x to a text file filename, creating the file as necessary. See File I/O.

8.164 write_to_path - Write to Path

```
write_to_path(filename, x)
```

Write the value x to a binary file filename, creating the file as necessary. See File I/O.

8.165 xbar - XBar

```
xbar(x, y)
```

Equivalent to x * floor y/x.

8.166 xkeys - Object Keys

xkeys(x)

Produce a list of keys for a map, table or list x.

```
KeRF> xkeys 33 14 9
  [0, 1, 2]
KeRF> xkeys {a: 42, b: 49}
  ["a", "b"]
KeRF> xkeys {{a: 42, b: 49}}
  ["a", "b"]
```

8.167 xvals - Object Values

xvals(x)

Produce a list of values for a map or table x. If x is a list, produce a list of valid indices to x.

```
KeRF> xvals 33 14 9
  [0, 1, 2]
KeRF> xvals {a: 42, b: 49}
  [42, 49]
KeRF> xvals {{a: 42, b: 49}}
  [[42], [49]]
```

9 Combinator Reference

9.1 converge - Converge

Given a unary function, apply it to a value repeatedly until it does not change or the next iteration will repeat the initial value. Some functional languages refer to this operation as fixedpoint.

```
KeRF> {[x] floor x/2} converge 32
0
KeRF> {[x] mod(x+1, 5)} converge 0
4
KeRF> {[x] display x; mod(x+1, 5)} converge 3
3
4
0
1
2
2
```

If a numeric left argument is provided, instead repeatedly apply the function some number of times:

```
KeRF> 3 {[x] floor x/2} converge 32
4
KeRF> 3 {[x] x*2} converge 32
256
KeRF> 5 {[x] join("A", x)} converge "B"
"AAAAAB"
```

Applied to a binary function, converge is equivalent to fold.

9.2 deconverge - Deconverge

deconverge is similar to converge, except it gathers a list of intermediate results.

```
KeRF> {[x] floor x/2} deconverge 32
  [32, 16, 8, 4, 2, 1, 0]
KeRF> {[x] mod(x+1, 5)} deconverge 1
  [1, 2, 3, 4, 0]
KeRF> 3 {[x] floor x/2} deconverge 32
  [32, 16, 8, 4]
KeRF> 3 {[x] x*2} deconverge 32
  [32, 64, 128, 256]
```

Applied to a binary function, deconverge is equivalent to unfold.

9.3 fold - Fold

Given a binary function, apply it to pairs of the elements of a list from left to right, carrying the result forward on each step. Some functional languages refer to this operation as foldl.

```
KeRF> add fold 1 2 3 4
   10
KeRF> {[a,b] join(enlist a, b)} fold 1 2 3 4
   [[[1, 2], 3], 4]
```

Note that the function will not be applied if folded over an empty or 1-length list:

```
KeRF> {[a,b] out "nope"; a+b} fold [5]
5
KeRF> {[a,b] out "nope"; a+b} fold 1 2
nope 3
```

It is also possible to supply an initial value for the fold as a left argument:

```
KeRF> 0 {[a,b] join(enlist a, b)} fold 1 2 3
  [[[0, 1], 2], 3]
KeRF> 7 {[a,b] out "yep"; a+b} fold 5
yep 12
```

The symbol $\/$ is equivalent to fold:

```
KeRF> add \/ 1 2 3
6
KeRF> 7 add \/ 5
12
```

Applied to a unary function, fold is equivalent to converge.

9.4 mapback - Map Back

Given a binary function, mapback pairs up each value of a list with its predecessor and applies the function to these values. The first item of the resulting list will be the first item of the original list:

```
KeRF> join mapback 1 2 3
[1,
  [2, 1],
  [3, 2]]
```

A common application of mapback is to calculate deltas between successive elements of a list:

```
KeRF> - mapback 5 3 2 9
[5, -2, -1, 7]
```

If a left argument is provided, it will be used as the previous value of the right argument's first value:

```
KeRF> 1 join mapback 2 3 4
[[2, 1],
[3, 2],
[4, 3]]
```

The symbol \~ is equivalent to mapback:

```
KeRF> 0 != \~ 1 1 0 1 0 0 0 [1, 0, 1, 1, 1, 0, 0]
```

9.5 mapdown - Map Down

Apply a unary function to every element of a list, yielding a new list of the same size. Some functional programming languages refer to this as simply map. mapdown can be used to achieve a similar effect to how atomic built-in functions naturally "push down" onto the values of lists.

```
KeRF> negate mapdown 2 -5
  [-2, 5]
KeRF> {[n] 3*n} mapdown 2 5 9
  [6, 15, 27]
```

Given a binary function and a left argument, mapdown pairs up sequential values from two equal-length lists and applies the function to these pairs. Some functional programming languages refer to this as zip, meshing together a pair of lists like the teeth of a zipper:

```
KeRF> 1 2 3 join mapdown 4 5 6
[[1, 4],
[2, 5],
[3, 6]]
```

mapdown also works with maps and tables:

```
KeRF> count mapdown {a: 1 2, b: 3 4 5, c: 6}
  [2, 3, 1]
KeRF> reverse mapdown {{a: 1 2, b: 3 4}}
  [[2, 1], [4, 3]]
```

The symbol \= is equivalent to mapdown:

```
KeRF> {[n] 3*n} \= 2 5 9
[6, 15, 27]
```

9.6 mapleft - Map Left

Given a binary function, apply it to each of the values of the left argument and the right argument, gathering the results in a list.

```
KeRF> 1 2 3 join mapleft 4
  [[1, 4],
  [2, 4],
  [3, 4]]
```

The symbol \> is equivalent to mapleft.

9.7 mapright - Map Right

Given a binary function, apply it to a left argument and each of the values of the right argument, gathering the results in a list. mapright, like mapdown, provides a way of "pushing a function down onto" data or overriding existing atomicity:

```
KeRF> 1 join mapright 2 3 4
  [[1, 2],
  [1, 3],
  [1, 4]]
```

mapright and mapleft can be used to take the cartesian product of two lists:

```
KeRF> 0 1 2 add 0 1 2
  [0, 2, 4]
KeRF> 0 1 2 add mapright 0 1 2
  [[0, 1, 2],
  [1, 2, 3],
  [2, 3, 4]]
```

The symbol \< is equivalent to mapright.

9.8 reconverge - Reconverge

Equivalent to unfold.

9.9 reduce - Reduce

Equivalent to fold.

9.10 refold - Refold

Equivalent to unfold.

9.11 rereduce - Re-Reduce

Equivalent to unfold.

9.12 unfold - Unfold

unfold is similar to fold, except it gathers a list of intermediate results. This can often provide a useful way to debug the behavior of fold.

```
KeRF> add unfold 1 2 3 4
  [1, 3, 6, 10]
KeRF> 100 add unfold 1 2 3 4
  [101, 103, 106, 110]
KeRF> {[a,b] join(enlist a, b)} unfold 1 2 3 4
  [1,
  [1, 2],
  [[1, 2], 3],
  [[[1, 2], 3], 4]]
```

The symbol $\setminus \setminus$ is equivalent to unfold:

```
KeRF> add \\ 1 2 3
  [1, 3, 6]
KeRF> 7 add \\ 5
  [12]
```

Applied to a unary function, unfold is equivalent to deconverge.

10 Global Reference

10.1 Math

10.1.1 .Math.BILLION - Billion

Constant representing $|10^9|$.

10.1.2 .Math.E - E

Constant representing Euler's number. 2.7182818284590452353602.

10.1.3 .Math.TAU - Tau

Constant representing 2π . 6.2831853071795864769252.

10.2 Net

10.2.1 .Net.client - Client

During IPC execution, contains a constant representing the current client's unique handle. See **Network** I/O.

10.2.2 .Net.on_close - On Close

If defined, an IPC server will call this single-argument function with a client handle when that client closes its connection. See **Network I/O**.

10.3 Parse

10.3.1 .Parse.strptime_format - Time Stamp Format

Specifies the format used for formatting and parsing dates and time stamps from delimited files when the field specifier is Z. Builds directly on the standard C function strptime(), as defined in time.h.

By default, %d-%b-%y %H:%M:%S.

- %b Abreviated month name
- %B Full month name
- %c Date and time
- %C Century 00-99
- %d Day of month as decimal number 01-31
- %e Day of the month as decimal number 1-31 with leading space for single digit
- %F Equivalent to Y-m-d ISO 8601
- %h Equivalent to %b
- %H Hours as a decimal number 00-23
- %I Hours as a decimal number 00-12

- %j Day of year as decimal number 001-366
- %m Month as decimal number 01-12
- %M Minute as decimal number 00-59
- %p AM/PM indicator, used with %I
- %S Second as integer 00-61; aka up to two leap seconds
- %u Weekday as a decimal number 1-7, Monday is 1
- %w Weekday as a decimal number 0-6, Sunday is 0
- $\mbox{\em \%W}$ Week of the year as a 00-53 with Monday as first day of week
- %y Year without century
- %Y Year with century
- %z Signed offset in hours and minutes from UTC
- %Z Time zone abbreviation as a character string

10.3.2 .Parse.strptime_format2 - Time Format

Specifies the format used for formatting and parsing timestamps from delimited files when the field specifier is z. Builds directly on the standard C function strptime(), as defined in time.h. Used for parsing time-only columns.

11 Programming Techniques

This section contains case studies illustrating how KeRF can be used to solve problems, ranging from simple to complex. We will build up solutions step by step and consider tradeoffs in performance and style.

11.1 Reversing a Map

A map links a set of keys with a set of values. It is easy and efficient to use a key to look up the associated value. Sometimes is desirable to go the other way- using a value to look up the associated key. One way to approach this problem might be to iterate through each key in the map until we found one which is associated with our target value:

```
def find_key(m, val) {
         keys: xkeys m
         for(i: 0; i < len(keys); i: i+1) {
              if (m[keys[i]] == val) { return keys[i] }
         }
        return null
}</pre>
```

As the number of keys in the map scales up, the amount of time this function takes to run increases proportionally. If we need to perform many repeated reverse lookups, this approach will be prohibitively slow.

As a general rule of thumb when programming, if something is too expensive to calculate, cache it. By writing a function which analyzes a map and constructs a new map which "reverses" the keys and values of the original, we can pay this construction cost once and then achieve efficient reverse-lookups.

There are several ways to approach this problem. A programmer used to imperative programming languages might come up with something like this:

```
def map_reverse_1(m) {
          r: {}
          keys: xkeys m
          vals: xvals m
          for(i: 0; i < len(keys); i: i+1) {
                r[vals[i]]: keys[i]
          }
          return r
}</pre>
```

Perhaps you want to get fancy and try to represent the same algorithm using the combinator fold?

```
{} {[m, e] m[e[0]]: e[1]} fold transpose([xvals m, xkeys m])
```

The simplest approach is to take advantage of the map built-in function:

```
def map_reverse_2(m) {
    return map(xvals m, xkeys m)
}
```

All of these solutions are making an unsafe assumption. The keys of a map are always unique by definition, but what happens if the values are not unique?

```
KeRF> map_reverse_2({a: "A", b:"B", c:"C"})
   {A:"a", B:"b", C:"c"}
KeRF> map_reverse_2({a: "A", b:"B", c:"A"})
   {A:"a", B:"b"}
```

We've lost information! A more robust map reversal routine should gather the keys of repeated values as a list, producing a result more like:

```
KeRF> map_reverse_3({a: "A", b:"B", c:"C"})
    {A:["a","c"], B:["b"]}
```

First, let's look at an imperative approach to solving the problem. We can iterate through the keys of the original map, as before. Instead of storing the key directly in the result map, we will append it to a list stored in the map. This requires us to first ensure that any slot in the result map is initialized with an empty list:

The enlist is important here- without it, string keys would be mashed together:

```
KeRF> join([], "foo")
    "foo"
KeRF> join("foo", "bar")
    "foobar"
KeRF> join([], enlist "foo")
    ["foo"]
KeRF> join(["foo"], enlist "bar")
    ["foo", "bar"]
```

We can simplify this slightly by using "spread assignment" to initialize our result map with empty lists in every entry:

```
...
r[vals]: [[]]
for(i: 0; i < len(keys); i: i+1) {
        r[vals[i]]: join(r[vals[i]], enlist keys[i])
}
...</pre>
```

What happens if we leave out this initialization entirely? Try it!

Now let's look at a functional approach to solving this problem. If we partition the value set of the original map, we obtain lists of the indices of the values which are identical:

```
KeRF> m: {a: "A", b:"B", c:"A"}
    {a:"A", b:"B", c:"A"}
KeRF> xvals m
    ["A", "B", "A"]
KeRF> part xvals m
    {A:[0, 2], B:[1]}
```

Since the key and value vectors produced by xkeys and xvals line up, we could also use those indices to obtain the corresponding keys for each group of values. KeRF's powerful indexing facilities make this simple:

```
KeRF> xkeys m
  ["a", "b", "c"]
KeRF> xvals part xvals m
  [[0, 2], [1]]
KeRF> (xkeys m)[xvals part xvals m]
  [["a", "c"], ["b"]]
```

Now we have what we need to assemble the result, so we use map to join the unique elements of the original value set with the lists of corresponding keys we computed previously. The unique function collects results in the order they appear, just like part, so everything will line up properly:

```
def map_reverse_4(m) {
    nk: unique xvals m
    nv: (xkeys m)[xvals part xvals m]
    return map(nk, nv)
}
```

Notice how we were able to use the KeRF REPL and a single working example to experiment interactively and then distill the results into a general definition. It is very natural to develop functional solutions to problems in this manner. Manipulating an entire data structure at once often results in a simpler solution with fewer conditionals and loops than trying to solve a problem "one step at a time".

It is also possible to write this as a more compact one-liner by avoiding intermediate variables and using some of the symbolic shorthands for map (!), unique (%), enumerate (^) and part (&), but the result is much harder to read and understand at a glance:

```
{[m] (%xvals m)!(^m)[xvals(&xvals m)]}
```

Shorthand is a nice way to save typing at the REPL, but favor a more relaxed, verbose style when writing larger programs- future maintainers (yourself included) will be thankful! Use KeRF's syntactic alternatives-infix function calls, optional parentheses, function aliases, etc.- to write your programs in the clearest, most readable way possible.

11.2 Run-Length Encoding

Run-Length Encoding (RLE) is a simple means of compressing data. Wherever there is a repeated run of identical elements, instead of storing each element store a single copy of the element and the length of the run.

For example, if our input list looked like:

```
"AAABBAAAAAA"
```

An RLE-compressed representation might look like:

```
[[3, `"A"], [2, `"B"], [7, `"A"]]
```

Let's start by writing a *decompressor*- given an RLE-compressed list, reconstruct the original. For a given element of the list, we can use take to create a run:

```
KeRF> p: [3, `"A"]
  [3, `"A"]
KeRF> take(p[0], p[1])
  "AAA"
```

One way to apply a binary function to a pair of arguments is to use the combinator fold. A fold is like placing a function between the elements of a list. Thus, these two expressions are equivalent:

```
KeRF> take fold p
  "AAA"
KeRF> p[0] take p[1]
  "AAA"
```

We really want to apply take to *each* pair in the original list. The combinator mapdown applies a unary function to each element of a list, returning a list of results:

```
KeRF> (take fold) mapdown [[3, `A],[2, `B],[7, `A]]
["AAA", "BB", "AAAAAAA"]
```

The parentheses are not required- in this case they are simply making it clearer that the function mapdown is applying to each element of the list to the right is "take fold". When combinators are attached to functions, they form new compound functions which can be passed around or stored in variables just like any other function:

```
KeRF> take fold mapdown [[3, `A],[2, `B],[7, `A]]
  ["AAA", "BB", "AAAAAAA"]
KeRF> take fold
  take fold
```

To reproduce the original sequence from this list of runs, we need to join all the runs together. The built-in function flatten does exactly what we need. Alternatively, we could use the equivalent join fold:

```
KeRF> flatten ["AAA", "BB", "AAAAAAA"]
  "AAABBAAAAAAA"
KeRF> join fold ["AAA", "BB", "AAAAAAA"]
  "AAABBAAAAAAA"
```

Putting everything together, we could write a definition for rle_decode in several ways:

```
def rle_decode(x) {return flatten take fold mapdown x}
rle_decode: {[x] flatten take fold mapdown x}
rle_decode: flatten take fold mapdown
```

This last approach is called a *tacit definition*- it doesn't require naming any variables or arguments. The combinators glue together functions to produce a function that is simply waiting for a right argument. Composing together functions won't always work out this nicely, but when a tacit definition is possible the results can be very aesthetically pleasing, as if there were hardly any syntax to the language at all:

```
KeRF> rle_decode: flatten take fold mapdown
  flatten take fold mapdown

KeRF> rle_decode [[3, `A],[2, `B],[7, `A]]
  "AAABBAAAAAAA"

KeRF> flatten take fold mapdown [[3, `A],[2, `B],[7, `A]]
  "AAABBAAAAAAAA"
```

Now that we're a bit more comfortable with using combinators, let's tackle the *compressor*- given a list, we want to break it into runs. For each run, we need to determine the first element (or any element, really) and the length of the run.

To find the start of each run, we can compare each element of the list with the item which came before it. If they're different, we are beginning a new run. Otherwise, we're continuing an existing run. The combinator mapback applies a function to each element of a list and its predecessor, which is just what we're looking for:

```
KeRF> != mapback "AAABBAAAAAA"
[`"A", 0, 0, 1, 0, 1, 0, 0, 0, 0]
```

Well, nearly what we're looking for. What's that character doing at the beginning of our result? mapback doesn't have anything to pair the first element of a list up with, so by default it leaves that item alone. If we supply a value on the left, mapback will use that to pair with the first element of the list on the right. Supplying a null will ensure that the first list element is considered "not equal to" this default value:

```
KeRF> `A != mapback "AAABBAAAAAAA"
  [0, 0, 0, 1, 0, 1, 0, 0, 0, 0, 0]

KeRF> `B != mapback "AAABBAAAAAAA"
  [1, 0, 0, 1, 0, 1, 0, 0, 0, 0, 0]

KeRF> `B != mapback "BAABBAAAAAAA"
  [0, 1, 0, 1, 0, 1, 0, 0, 0, 0, 0]

KeRF> null != mapback "AAABBAAAAAAA"
  [1, 0, 0, 1, 0, 1, 0, 0, 0, 0, 0]
```

The function which, given a boolean list, produces a list of the indices of the 1s. If we index into the original list, we can retrieve a list of the items which begin each run, in order:

```
KeRF> s: "AAABBAAAAAA"
    "AAABBAAAAAAA"

KeRF> null != mapback s
    [1, 0, 0, 1, 0, 1, 0, 0, 0, 0, 0]

KeRF> which null != mapback s
    [0, 3, 5]

KeRF> s[which null != mapback s]
    "ABA"
```

Now we just need to find the lengths of each run. Let's consider that vector we already created which identifies run heads. If we take a running sum (rsum) of that list, we can uniquely label all the members of each run:

```
KeRF> h: null != mapback s
  [1, 0, 0, 1, 0, 1, 0, 0, 0, 0, 0]
KeRF> rsum h
  [1, 1, 1, 2, 2, 3, 3, 3, 3, 3, 3]
```

Partitioning these labels will conveniently group them together, and we can count each of the resulting groups:

```
KeRF> part rsum h
1:[0, 1, 2], 2:[3, 4], 3:[5, 6, 7, 8, 9, 10, 11]
KeRF> count mapdown part rsum h
[3, 2, 7]
```

With the list of counts and the list of values, we can join each to produce the tuples we want. By giving the combinator mapdown a left argument and a binary function, we can neatly "zip" together our lists:

```
KeRF> 1 2 3 join mapdown "ABC"
  [[1, `"A"],
  [2, `"B"],
  [3, `"C"]]
```

Bringing everything together, we can arrive at a definition like this:

```
def rle_encode(s) {
    heads: null != mapback s
    vals: s[which heads]
    counts: count mapdown part rsum heads
    return counts join mapdown vals
}
```

For the sake of comparison, here's an imperative solution:

```
def rle_encode_2(s) {
    r: []
    c: 1
    for(i: 0; i < len(s); i: i+1) {
        if (s[i] != s[i+1]) {
            r: join(r, enlist [c, s[i]])
            c: 1
        } else {
            c: c+1
        }
    }
    return r
}</pre>
```

Which of these is easier to understand and reason about? The imperative program is familiar, but involves a number of variables which continuously change throughout execution. Did we make any off-by-one errors? The functional solution replaces loops and conditionals with built-in functions and combinators, and never changes the contents of a variable once it is assigned.

"Readability" is inherently subjective, so let's compare performance:

```
KeRF> data: 10000?"ABCD";
KeRF> timing 1;
KeRF> rle_encode data ;
   21 ms
KeRF> rle_encode_2 data ;
   781 ms
```

KeRF executes the functional solution substantially faster. Combinators and built-in functions which operate on entire lists at once are highly optimized and have very little interpreter overhead, so an individual operation can approach native execution speeds. Explicit loops and conditionals force the interpreter to do most of the heavy lifting, which is less efficient.
